Gonorrhœal Cerebro-spinal Meningitis.—Dr. Stiénon (*Journ. de Méd.*, Bruxelles, No. 9, 1892) relates a case of cerebro-spinal meningitis in a young man, which, according to the author's views, was due to the location in the cerebro-spinal meninges of gonococci from a urethritis which was found present, just as the germs of epidemic cerebro-spinal meningitis, typhoid fever, erysipelas, acute rheumatism, etc., are capable of vegetating in this region and developing their effects. The occasional production of arthritis, peri- and endo-carditis, periostitis, and neuritis, from the presence of this micro-organism, plead in favor of the author's hypothesis, and permit the conclusion that while meningeal manifestations from gonorrhœal infection are very rare they are by no means impossible.

Chemical Research on Addison's Disease.—Following out the researches of Foa and Pellacani, by which it was shown that the aqueous extract of the supra-renal capsule was capable of producing speedy death, and the subsequent analysis which went to show that the poisonous property was due to neurine, Drs. Marino-Zuco and Dutto (*Bull. di R. ac. Med. di Roma.*, Nos. 4, 5, 1891), looking upon Addison's disease as a slow intoxication process due to the neurine, which is no longer absorbed by the altered or destroyed supra-renal capsules, have made a study of the urine in a patient thus affected during the last twelve days of his life. The reaction of the urine was acid and contained neither albumin nor sugar. A noticeable quantity of indican was shown, and after long and careful manipulation the presence of neurine was clearly demonstrated. Both supra-renal capsules were found destroyed, and there was tuberculosis of both lungs.

Clinical Department.

A CASE OF PALIMPTOSIS, ALTERNATING WITH PROPTOSIS, FOLLOWING INJURY.

H. DAVISON SCHWARZSCHILD, M.D.,

NEW YORK.

THROUGH the courtesy of Drs. Webster and Carey, in whose clinique, at the Manhattan Eye and Ear Hospital, the patient with the above-named disease presented himself, I am enabled to present the data and notes of a most interesting and rare condition, which will add one to the many obscure diseases now extant.

Martin D——, aged twenty, by occupation a coachman, informed me that at the age of eight years he was violently thrown from a wagon and struck his forehead on the ground; that the wound healed without any trouble, no abscess following. A small scar still remains at the site of the injury, a trifle to the right of the supra-orbital notch, on the right superciliary ridge

The patient's history is defective, and I am unable to obtain any facts in addition to those mentioned. The condition of which I intend writing was the immediate consequence of the injury. Upon inspecting the patient's face the asymmetry is evident, the left side of the head, from the malar bone to the parietal eminence, is more prominent than the right side; but the point of interest lies in the condition of the right orbit. The appearance is that of prothesis oculi, but a close examination shows that there is a natural eye deeply seated in the orbit; comparing this with the other side, I found that the right eye was situated 6 mm. deeper in the orbit than the left eye. The free border of the supra orbital arch is 9 mm. from the top of the eye, leaving a hollow into which the lid sinks, forming a cul-de-sac. The little finger can be insinuated into this cavity and pushed back 2 ctm. (¾ in.)

The palpebral fissure is 4 mm. wider than the left; this serves to show that a partial absorption of the orbital process of the frontal bone has taken place, and from the negative history of abscess and ulceration, and from the small size of the scar, I conclude that neither acute periostitis nor necrosis occurred, and that the change is one either of arrest of growth or of atrophy of the bone, or of both combined.

As regards the sinking in of the eye (palimptosis) this is readily explained by the absorption of the fascia tarso-orbitalis, the absence of the fatty cushion being readily appreciated by palpation.

The described condition of affairs does not seem to have caused him any great inconvenience, and it was only on account of a bulging out of the eye, accompanied by local pain referred to the posterior portion of the eye, that he sought assistance. He also mentions that he has occasional slight occipital headache. Whenever he inclines his head forward, at right angles to his body, the eye bulges, using the roof of the orbit as an inclined plane, pushes the upper lid in front of it, and when the maximum point of proptosis has been attained, the eye has emerged 12mm. from its former position, being now 6 mm. in advance of its fellow.

I observed while this phenomenon occurred that the ocular conjunctiva appeared slightly congested, immediately to return to its former normal condition when the patient raised his head and the eye sank back into the former position of palimptosis.

Some of my readers may consider that the upper lid, following the movement of the eye, simulates v. Graefe's sign of the proptosis of Basedow's disease, and in order to elucidate the matter, I wish to state that when the eye is in its deep-seated position the upper lid maintains its normal mobility and is pushed forward by the advancing eye in a purely mechanical manner.

Examination of the right eye: The eye is of normal size, the cornea, iris and conjunctiva normal. Tension normal. O. D, V. $= \frac{20}{20}$ —; emmetropic (Ophth.). O. S., V. $= \frac{20}{30}$ —; $\frac{20}{20}$ w. — 0.75 D. Sph.; error of refraction being anisometropia. Javal Ophth.: O. D., 0.5 D.; astigmatism 90 or 180 w. R. O. S., 0.75 D.; astigmatism 90 or 180 w. R. Muscular test, Stevens' method: Hyperphoria Rt. 1°, Esophoria 2°; adduction 16°; abduction 5°; sursumduction Rt. 4°; sursumduction Lft. 2°.

Ophthalmoscopic Examination.—*Direct and Indirect Methods.*—Fundus normal. No pulsation of veins or arteries. Relative size of vessels normal. Optic disk normal in color and size; but to its temporal side presents a slightly whitish appearance, with a crescentic outline, the diameter of which arc (direct method) is 2 mm. diminishing to 1 mm. at the periphery of the disk. It is to be understood, that the whitish appearance is in the papilla, to its outer side, the papilla being normal in shape, viz., circular. Scleral ring is fairly well marked. Upon closest examination it was impossible to detect anything in any way abnormal or anomalous. The peculiar shading of the disk would probably have escaped notice, had not the case been such an extraordinary one, and one in which the most scrutinizing examination was called for. I could neither see nor feel any pulsation, no aneurismal bruit could be heard; no tumor or swelling of any kind was felt. The patient, although pale, appears to be well nourished and strong, not neurasthenic; has a pulse of ninety, and regular; no cardiac murmur nor enlargement of the thyroid gland; no evidence of specific disease.

In the condition described, it is not the diagnosis which is of most value, but the etiological factor which must be ascertained. The palimptosis I have endeavored to explain by stating that the cavity of the orbit is deepened by the absorption of the cellular tissue; it now remains to explain the proptosis.

Theory No. 1.—As a result of the injury, besides the partial absorption of the portio orbitalis of the os frontis, and of the orbital fascia, a communication was established between the frontal sinus and the orbit through which air entered, thereby destroying suction, which undoubtedly, normally, assists in maintaining the eyes in position. It is a question whether this opening still exists or whether it closed shortly after the injury; the opening, if it exists, must be very small, as a careful examination fails to demonstrate its presence.

The condition of aero-orbita exists, however, whether the wall is still fenestrated or not, and this is manifest, for as soon as the centre of gravity of the eye changes, as it does when the head bends forward, the eye emerges, being attracted by gravitation, and stops only when compelled to do so as a result of its muscular attachment. The pain experienced during advancement of the eye, is due to one of three conditions, or possibly all combined: 1, Muscular strain; 2, air pressure; 3, blood pressure.

Theory No. 2.—Magnus[1] mentions briefly that a case of periodical proptosis has been observed on bending the head, as the result of varicose dilatation of the orbital veins. It is possible that a like condition may exist in this case, although here this occurs at all times, whenever the head is inclined; and I can hardly believe that a varicose vein will so greatly diminish in size, as to permit of the eye being in the position of palimptosis; also I should expect to find considerable chemosis and dilatation of the retinal veins and venæ vorticosæ, with hyperæmia of the retina, and probably also a pulsation, none of which were evident upon examination of the fundus in the erect posture. Hence, my non-belief in this theory, although I do not attempt by any means to deny its tenability.

The following three diseases—aneurism of the ophthalmic artery (branch of the internal carotid artery), aneurism of the middle meningeal (branch of internal maxillary), and arterio-venous communication in the cavernous sinus—cannot be considered as etiological factors, as their principal symptoms, viz., proptosis with pulsation, chemosis and engorgement of the veins, are not present in the case which I have described. The same objection exists as regards Basedow's disease, which presents many points of dissimilarity, which disease is of neurotic and not traumatic origin, and possesses many concomitant symptoms which do not belong to my case.

Treatment.—In concluding, a few words should be mentioned as regards our ability to relieve the condition. Treatment may be either conservative or radical; the former is decidedly more rational. I should suggest a pair of spectacles such as are used for driving, namely, with wire sides; on the right side this should be in close apposition with the eye, and by a suitable padding produce sufficient pressure to maintain the eye *in situ*, when the patient stoops. The spectacle can be kept tightly in contact with the eye, by means of a "temple" which can be wound back of the ear, and will remain there if sufficiently tight. The radical or operative method would be to make an incision into the orbit and relieve, if possible, the pathological condition. This is a method of procedure which may be followed by an orbital cellulitis, and on account of its danger I do not favor it.

Medical literature does not throw any light on the subject, and, after having searched all the ophthalmological works to which I had access, I came to the conclusion that it has been the good fortune of very few, if of any, medical men to observe such a phenomenally rare case, and Dr. Webster, whose vast experience and great ability we all acknowledge, informs me that he has never seen a case parallel to this. I have previously quoted Magnus' brief statement regarding periodical proptosis.

Schmidt-Rimpler[2] mentions enophthalmos (his word), following absorption of the orbital cellular tissue. He does not state whether it is a senile atrophic condition, this being a comparatively common occurrence, or not.

Dr. Eugene Smith, an oculist of Detroit, informed me personally of a case of congenital palimptosis due to an arrest of development of the cellular tissue.

[1] Schmidt-Rimpler's Ophthalmology, p. 532. [2] Ibid., p. 532.

Every work on ophthalmology contains chapters which bear relation to the subjects of proptosis with pulsation, and proptosis of Basedow's disease, but as these are irrelevant to the case at hand, quotations are unnecessary; but in no work have I succeeded in finding any clause or paragraph which relates to the case that I have the honor of naming and describing as palimptosis alternating with proptosis due to traumatism.

In conclusion, I desire to state that I saw the patient but once and that under unfavorable circumstances, viz., in the dispensary on a busy day, and although I should have liked to have examined his eye with the ophthalmoscope when he inclined his head, I did not find it practicable to do so, and had to content myself with a thorough examination in the erect posture.

Hotel Endicott, Columbus Avenue and Eighty-second Street.

OPERATION FOR MOVABLE KIDNEY.

By C. O. BAKER, M.D.,

surgeon to the otis private hospital, auburn, n. y.

Reported by SUSAN G. OTIS, M.D., House Surgeon.

The patient, Angus Mac——, M.D., M.R.C.P., London; at present a resident of Santa Clara, Cal.; aged forty-five; weight one hundred and thirty-three pounds; nervo-bilious temperament; family history excellent. Had always enjoyed comparatively good health, suffering occasionally from attacks of indigestion.

In 1879, during a sea voyage lasting forty-seven days, in which he was constantly sea sick, he discovered a movable, rounded, smooth, and painless tumor in the right hypochondrium. In the recumbent position it could not be felt, but by pressing the diaphragm downward, or on standing erect, it descended about one inch below the end of the twelfth rib, and midway between that point and the median line. From that time until the present he suffered almost constantly from tenderness over the liver and stomach, front and back, indigestion with all its concomitants of flatulence, pain, constipation, etc., causing the ascending colon to become excessively distended. During the winter of 1888 there was suppression of bile with characteristic clay-colored stools, recurring from time to time and lasting from one to three days, and on one occasion four weeks. There never was any jaundice or evidence of the presence of bile in any of the secretions. In September, 1887, broken down in health, he relinquished the practice of his profession and settled in Southern California.

During the nine years extending from 1879 to 1888 the tumor had not changed in size, shape, or character. Its mobility was however much greater, hence its interference with the functions of surrounding organs increased. While in the recumbent posture or lying on the right side there was complete immunity from pain and discomfort. In standing, riding, or walking, there were dragging pains, and general suffering along the right side from the hypochondrium to the iliac region, with shooting pains around the back and pelvis, rendering it necessary for the patient to lie down to get relief. For years he was unable to lie on the left side, as the tumor invariably pressed on the pylorus, causing great gastric distress with intense pain around the back.

The patient consulted many of his confrères regarding this tumor, and received a great many different opinions; and not until May, 1888, when he visited Professor Osler, in Philadelphia, was a diagnosis of movable kidney made. Professor Osler's opinion was corroborated by the late Dr. D. Hayes Agnew, of that city, but he declined to do nephrorrhaphy, regarding it as a dangerous and unsatisfactory operation. All sorts of appliances (mechanical and otherwise) were tried, without avail. In March, 1890, the patient consulted Mr. Lawson Tait, F.R.C.S., of Birmingham, by letter, and in May visited that eminent surgeon, who expressed the opinion that the tumor was a gall-bladder distended with gall-stones, ignoring the previous diagnosis, and repudiating the existence of such a condition as movable kidney; saying in his letter: "I am very sceptical about such cases of it altogether, because in all cases so far that have been sent to me for the purpose of operating upon it, the condition when the abdomen was opened was found to be altogether different, generally impacted gall-stones in the neck of the gall-bladder." Yet, strange to say, three operations on movable kidney are reported in the Birmingham *Medical Review* as made by Tait in 1886. He made an exploratory incision over the gall-bladder, but found that organ healthy, as also the adjacent structures, and the "kidney in situ." He afterward said the tumor was an hysterical tumor.

Nearly two more years of suffering ensued, when the patient determined, after consulting Dr. Senn, of Chicago, and others, on one more effort to regain health. He was operated upon in a private hospital in Auburn, N. Y., by Dr. C. O. Baker, January 18, 1892. The patient was etherized, and placed upon the left side with a pillow so placed as to extend the space at the site of operation. An incision was made from the lower border of the twelfth rib, beginning about one inch from the external border of the erector spinæ and extending to a point one inch posterior to the anterior superior process of the ilium, in length three and one-fourth inches, and down through the latissimus dorsi, the fascia of the internal oblique, and transversalis and external edge of the quadratus lumborum. The underlying fat was divided and search made for the kidney, which was found to be so high up under the liver that it could not be easily reached by the fingers with the patient lying on the side or back, and could only be reached by placing him in a sitting position, when it was secured and brought down by a tenaculum, an act requiring considerable force.

Finding a large, roomy capsule of fat in which the kidney moved about freely when the man was about, it was gathered up and quilted together below the organ with a small circular needle armed with kangaroo tendon, the suture was tied and cut short. Two large kangaroo tendons were passed through the deep muscles and kidney, bringing them out on the opposite side of the wound in the same manner. Then one silkworm gut suture was passed deeply through the muscles and kidney (probably three-fourths of an inch deep in the kidney). These sutures were then drawn tight and tied.

The kangaroo ends were left buried, the silkworm-gut ends extending out through the opening. Then a large perineum needle was passed through the skin about three-quarters of an inch from the line of the incision, including the kidney capsules, and all tissues, brought out the same distance on the opposite side of the wound on a parallel line with, and close to, the lower border of the twelfth rib. Then a large kangaroo tendon was drawn through and tied, including the skin. This left the extremity of the kidney one-half inch below the lower border of the twelfth rib, and firmly fixed. A small drainage-tube was placed, and the wound treated as an open wound.

January 19th.—Urinated 12 midnight and 2 A.M. Some blood in urine. 6 P.M., temperature normal; passed six ounces urine, somewhat bloody. Wound dressed. Dressing saturated with serous fluid, having a strong smell of urine.

January 21st.—Temperature normal, urine increasing, slightly stained with blood.

January 22d.—Urine normal.

January 23d.—Removed the drainage-tube. Discharges ceased. Temperature normal; pulse 70. Urine increased in quantity and normal in appearance. The patient was kept in bed twenty-eight days, with no unfavorable symptoms, and no suffering except some pain caused by flatulence and indigestion.

On February 29th, he began the journey to California. He reached there in five days, and after recovering from

the fatigue of the journey reports himself gaining in strength and entirely free from his old trouble.

The tendon suture which was tied externally was absorbed in eighteen days. The silkworm-gut suture was left in and protruded, but has not at this date been removed.

RUPTURE OF THE UTERUS CAUSED BY DIVULSION.

By FRANK H. MURDOCH, M.D.,

PITTSBURG, PA.

Two years ago a patient came to me with the following history: Mrs. A——, aged thirty-five, married, never had been pregnant, appetite poor, had painful diarrhœa most of the time, and suffered intense pain for a few days previous to and during menstruation. Examination showed so much constriction at inner os that the smallest sized probe would pass only immediately after the cessation of the menstrual flow. The depth of the uterus was two and a half inches. Rapid dilatation was done under ether to the extent of an inch, twenty minutes being occupied in the operation. Result—First, menstrual period painless; second, slight pain, and third, pain quite severe. I decided to dilate again, more rapidly, and use a stem. The patient was anæsthetized. Goodell's dilator was introduced, and at the end of five minutes the dilatation was carried to the extent of $\frac{7}{8}$ of an inch. At this point the patient began to breathe through the uterus, the air entering and leaving the peritoneal cavity making a distinct blowing sound. Rupture of the fundus of the uterus at once suggested itself. I withdrew the dilator, and with the utmost care and gentleness introduced a sound into the uterus, allowing it to enter five inches, thus confirming the diagnosis of rupture. At this time the patient's pulse was ninety and jerky, and her face was bathed in cold perspiration. The treatment consisted in swabbing the cervical canal with tincture of iodine, dusting the cervix with iodoform, and introducing a strip of iodoform gauze into the uterus for drainage, holding it in position by means of a vaginal tampon of boroglyceride. She was given a hypodermic of morphia and put to bed. Her bowels were kept open once a day with Rochelle salts, turpentine stupes were applied to the abdomen, and six minims of Magendie's solution of morphia were given twice a day hypodermically to relieve pain. The tampon and iodoform gauze were removed on the second day. There was very little distention of the abdomen at any time, and only slight tenderness. The pulse never rose above 100 nor the temperature above 100½° F.; in fact she made an uninterrupted recovery. Her menstrual periods since the last dilatation have been comparatively painless, she has gained flesh, her diarrhœa has ceased to trouble her, and she considers herself well. She has not become pregnant.

Remarks.—The subject of rapid dilatation of the uterus naturally divides itself into three parts—first, rapidity of dilatation; second, extent of the dilatation, and third, the danger of the operation.

Rapidity of the Dilatation.—In regard to this question there is a great diversity of opinion. Dr. Goodell[1] screws the handles quickly together so that some of the constrictor fibres are ruptured sometimes audibly. Dr. Grandin[2] divulses the cervix in five or six minutes. Dr. Strong[3] believes that twenty to forty minutes should be the average time, and Dr. Townsend[4] advises that the dilatation be accomplished more or less gradually and not by rude, quick measures.

Extent of the Dilatation.—Drs. Ball,[5] of Brooklyn; Goodell and Ellwood Wilson, of Philadelphia; Hands and Watts, of New York, forcibly dilate the uterus under ether to the utmost limit. Dr. Townsend[1] dilates one inch, Dr. Strong[2] one and one-fourth to one and five-eighth inches, and Dr. Skene[3] dilates to the extent of admitting a No. 10 or 12 English sound.

Danger of the Operation.—Among those who consider the operation to be comparatively free from danger may be mentioned Drs. Wathen,[4] Goodell,[5] and Strong,[6] while others, as Skene,[7] Fritsch,[8] and Goelet[9] regard the operation as a dangerous one. Now, it seems to me that the extent of the dilatation, at least in the case of uteri that have never been impregnated, should govern the rapidity of the operation, for the danger evidently lies more in the rapidity with which the dilatation is accomplished than in the extent to which it is carried. If the dilatation is to be carried only to the extent of one-half an inch, it matters little how rapidly it is done, but if it is the intention to dilate an inch or more, it is safer to take plenty of time, else the operator may find himself, as I did, in uncomfortably close proximity to a ruptured uterus.

HICCOUGHS CURED BY PRESSURE UPON THE SUPRA-ORBITAL NERVES.

By A. M. BELT, M.D.,

BALTIMORE, MD.

W. L——, when wrestling on March 24th, was thrown, striking his head against a wall. The following morning he consulted a doctor with regard to his fallen palate. In the afternoon hiccoughs commenced and continued six days, when I was sent for. I found the man hiccoughing twelve to fifteen times per minute, with a forlorn and worn-out expression of countenance. As there was quite an array of medicine near by, instead of giving a prescription I applied my thumbs to the supra-orbital nerves, and within three minutes the hiccoughs were completely checked. They returned fifteen hours afterward, when pressure was again applied and the hiccoughs were suppressed for nine hours. The third and last time pressure was applied the hiccoughs disappeared to return no more.

FRACTURE OF THE FEMUR FROM MUSCULAR ACTION.

By AUGUSTUS J. BURTON, M.D.,

NEW YORK.

I THINK the following case will prove of interest. It occurred in a healthy, well-developed boy aged sixteen. He was playing ball, and was batting the ball out in the game called "fungos." He had tossed the ball in the air and was about to strike it on its return, when he fell; not that he slipped or there was any extraneous cause for it, but, as he says, he could no longer support himself, and had to drop to the ground. He felt nothing give way. His fall seemed so entirely without cause that his playmates thought he was joking. He was carried home, and upon examination I found the left femur broken, the point of fracture being at about the junction of the upper and middle third and the line apparently oblique, extending from within upward and outward. The muscles that would seem to have produced the fracture were the flexors and adductors of the thigh, as in the act he was about to perform there would be a sudden and severe demand upon the muscles that flex the body upon the left thigh and rotate it to same side.

PUBLISHERS

WM. WOOD & CO., 43, 45 & 47 East Tenth Street

New York, May 14, 1892.

THE PATHS OF SENSORY CONDUCTION IN THE SPINAL CORD.

A QUESTION of very great interest to physiologists, and one of some practical importance to the physician, is that of the course of the sensory paths in the spinal cord, and the effect of lesions cutting the cord in half. This subject has recently been studied anew by Rossolymo, Gotch, Horsley, F. W. Mott, and Turner, with results which, if not conclusive, at least bring us a little nearer the solution of the problem. Gotch and Horsley employed a new and original method. It consisted in tapping the spinal cord at its lower part, connecting the substance with an electrometer, irritating the sensory nerves below the tapped level, and noting the degree of electrical change produced in the cord by the ascending impulses. They found that a greater electrical disturbance, and consequently greater amount of nerve-impulses, passed up on the same side as the irritation, in the proportion of about 80 to 20. The disturbance was greater in the lateral columns.

These experiments did not show, however, what kind of afferent impulses passed up the cord, and as a great many of these do not reach consciousness and arouse sensations, nothing very definite in regard to sensory conduction was established by their experiments.

Dr. Mott's investigations were made upon monkeys by hemisections of the spinal cord at different levels. His object was to determine the question of the decussation of cutaneous and muscular sensations, as well as their paths of conduction. There are at least seven different views held regarding these points. Ferrier thinks that all forms of sensation decussate immediately and pass up in close relation with the gray matter of the cord. Brown-Séquard thinks that all forms of sensation, except muscle-sense, decussate immediately and pass up in various channels. Schiff thinks that painful impressions decussate and pass up the gray matter, while tactile sensations do not. Woroschiloff and Miescher think that most sensory impulses decussate, and that the paths of conduction are in the lateral columns. Weiss, Homen, and Osawa think that painful sensations pass up the lateral columns about equally on the two sides; while Horsley and Gotch find that most afferent impulses pass up on the same side. With this rich variety of opinion, the clinician may indeed be pardoned for feeling some uncertainty in attacking problems of spinal diagnosis.

Dr. Mott's experiments lead him to believe that pain and temperature sensations originating on one side pass up on each side of the cord, while tactile and muscular sensations pass up on the same side as the irritation.

The general opinion of clinicians has long been favorable to the Brown-Séquard view of the conduction of sensory impulses. The evidence from disease on man is, after all, the most conclusive and most satisfactory, and such evidence on the whole supports the original teaching of Brown-Séquard.

Dr. Turner's experiments, which seem to have been conducted with as much care as those of Dr. Mott, bear out this view also. They appear to show, however, that in the upper part of the cord the decussation may not be so complete as it is lower down. A study of Dr. Mott's cases does not necessarily negative this view.

With regard to the tracts of conduction, the secondary degenerations following hemisection of the cord, also, on the whole bear out the view of Edinger, that the nerves of cutaneous sensation pass to cells in the posterior horn, thence through the commissures to the opposite side. It is probable that pain and temperature sensations pass up in the antero-lateral tract of Gowers; that tactile sense passes up in the ventral and outer part of the posterior horn and in the deeper part of the lateral column near the gray matter. There is probably some variation in this respect at different levels of the cord.

We may, on the whole, consider that experimentation supports clinical experiences in establishing the reality of the Brown-Séquard theory, and of the Brown-Séquard paralysis.

FIVE THOUSAND MORE.

So far, fifty-five medical colleges in this country have graduated two thousand five hundred and sixty-eight students. As there are over seventy-one more colleges to hear from, the supply of doctors this year is likely to equal the demand. At present rates five thousand new doctors seems a reasonable expectation, and their work among the sixty odd millions of our population is something to be looked forward to with interest.

Meanwhile the hundred thousand doctors already at work must brace themselves for the conflict with freshly equipped rivals.

In looking over the records of medical students and graduates in the last twenty years, we note a gradual increase, from about six thousand in 1870–71, to over thirteen thousand in 1888–89. About every decade there is a slight lull. Thus in 1872 the students fell off nearly one thousand, and in 1883–84 they fell from thirteen thousand to twelve thousand. Since 1884–85 the increase has been steady, the annual rate being from five hundred to one thousand; and in 1891–92 there were probably fifteen or sixteen thousand medical students in this beautiful and healthful land.

The increase is largely due to the establishment of new schools. The number of students in the older colleges keeps slightly increasing; but the elevation of standard drives many students to cheaper colleges with shorter courses. In fact, the elevation of the standard of teach-

ing has apparently been a boon to the poorer colleges. This result, however, will be only temporary, for the State restrictions on medical practice, and the increased intelligence of the public regarding medical matters, makes it constantly more imperative that students get a good education before starting in practice.

THE ELECTRICAL CURE OF CANCER.

In the year 1889, and again in 1890, Miss Emily Faithfull had the misfortune to require treatment for epithelial cancer. Both operations were attended by a relapse. When it came time for a third operation the possible utility of electricity was suggested to her. It was tried, and she announces that the result so far has been "absolutely satisfactory." Influenced by this fact the lady has gone to work, and with a good deal of literary skill, if not of critical acumen, she has compiled all the facts she could find bearing on the subject of the treatment of cancer by electricity. Her paper, though published in the *Contemporary Review*, would be no discredit to a medical journal, except that she seems to have found in literature only those references which more or less support her view of the probable efficacy of the agent about which she shows so keen an interest. We have carefully read over her quotations, and must confess that, after all, they do not furnish any very definite data. The most pronounced effects, and those which are secured by a rational method, are recorded by Dr. Inglis Parsons, and they have already been referred to in these columns. Dr. Parsons's paper, however, though published three years ago, has not been followed by favorable reports from others, though these would pretty surely appear if all he claimed were true.

Modern surgical pathology has reached this conclusion, that cancer is a local disease, and that early, extensive, and thorough operation gives, in a good many cases, curative results. This is about all the progress that has been made in the therapeutics of cancer. Still we shall be very glad to learn that electricity has been of radical service to Miss Faithfull.

NEW YORK AND ST. PAUL.

Two things much impressed that eminent and observant author, Mr. Rudyard Kipling, while making a tour of the "States;" on the one hand, the unkemptness and misrule of New York; on the other, the scarlet-fever signs of St. Paul. Concerning the first he says, among other things, this: "It is neither seemly nor safe to hint that the government of the largest city in the States is a despotism of the alien by the alien for the alien, tempered with occasional insurrections of the decent folk. Only the Chinaman washes the dirty linen of other lands."

But to St. Paul, after discoursing upon the beauty of its suburbs, he gives this final tribute of respect and admiration: "One little brown house at the end of an avenue is shuttered down, and a doctor's buggy stands before it. On the door a large blue and white label says 'Scarlet Fever.' Oh, most excellent municipality of St. Paul! It is because of these little things, and no rowdying and racketing in public places, that a nation becomes great, and free, and honored. In the cars to-night they will be talking wheat, girding at Minneapolis, and sneering at Duluth's demand for twenty foot of water from Duluth to the Atlantic, matters of no great moment compared to those streets and that label."

Mr. Kipling lays great stress, and properly, upon the importance of preventing scarlet fever. New York, however, does not deal with this problem in any backward or unintelligent spirit. The use of the sign may answer for suburban localities, but its introduction into large and crowded cities has not yet proved to be wise or practicable. New York furnishes some excellent illustrations of smart politics and stupid citizenship, but in the matter of sanitation and public health there has been little to criticise.

ESSENTIAL DROPSY.

Modern authorities on pathology are inclined to smile at the possibility of such a thing as "essential dropsy;" Barthez and Rilliet, however, devote a chapter to this subject. Besnier, Straus, Legroux, and other writers in the Encyclopædic Dictionaries of Deschambre and Jaccoud, admit the existence of a form of dropsy which is not dependent on any of the ordinary or known causes, and which may be called essential until more is discovered regarding it. Dr. Edouard Tordens has reported a typical case of this kind in the *Archives de Méd. Belg.* The patient, a boy of seven, was taken, without known cause, with a chill, fever, lassitude, and headache, followed by œdema of the lower extremities. This œdema rapidly extended upward until anasarca was general. Some fluid was found in the pleural and peritoneal cavities also. There was no eruption, no sore throat, no heart trouble, no headache or vomiting. The urine was normal and free from albumin and casts, nor was anything morbid ever found in it, though it was examined daily for a month. The patient gradually improved, and in about six weeks was entirely recovered. Dr. Tordens reports the case as one of essential dropsy, and he explains it upon a theory of a vaso-motor paralysis leading to atony and leakage of the vessel-walls.

THE TITLE OF PROFESSOR AND DOCTOR.

Mr. Huxley, says *The Lancet*, though M.D. of Breslau and M.B. of the University of London, and the happy possessor of endless doctorates of all sorts, objects to the title of "Dr." Huxley. He can stand being called Professor, but draws the line at "Dr.," which many men seem to value so highly.

The Lancet seems to think it very natural that so great a man as Dr. Huxley should not wish to be called "doctor." It strikes us as partaking a little of snobbishness. The truly great man will not be very much concerned whether the title usually given him is "Mr." or "Major" or "Dr." or "Professor." The Hon. Chauncey M. Depew bears the indignity of a doctorate genially, and does not complain when addressed by his title. There have been other great men who were called doctors; so let Dr. Huxley not worry lest he be occasionally thought a member of the unworthy throng. Or if he is really distressed, there is, we are told, a prospering organization in this city "for the suppression of the title of Doctor among medical men." Let him join their ranks.

THE LAST OF TSANG-DING.

DING was a leper. In the RECORD of January 23d, we spoke of him and of the trouble he was causing the city authorities. He will cause them no more. On Friday night last he died. Alone. Away from friends, from home, separated from his country by a vast expanse of water, from his countrymen and fellow-men by the power of public sentiment; deprived of the comforts accorded the sick criminal by the inadequacy of provision on the part of the Government for the care of lepers, a prisoner in a secluded tent, left to live by himself and to die alone; we may well say, as we think of him in that neglected tent on a dreary island, *armes Ding*. Lo, the poor and much-abused Indian lives in history. He had a certain nobility which keeps his memory green. There is nothing very noble about a leprous Chinaman, and Ding's name will die with him. Poor Ding!

DOG-SERUM IN PHTHISIS.

THE attempts, chiefly made by French investigators, to secure a "vaccine" against tuberculosis have the merit of ingenuity, and appear to prove also some important facts in the production of immunity. Dr. J. Héricourt, in the *Archives Générales de Médecine*, has recently described the results of his work in treating the tuberculous with the blood serum of dogs. The results present the same story—relief and cure of cases in the first stage, amelioration of cases in the second and third stage. In other words, the dog-serum was of no specific value whatever. However, there was one exception in which a case remained cured. It was one in which the dog whose serum was used had first been vaccinated against tuberculosis. It was found that dogs inoculated with bird-tuberculosis became refractory to human tuberculosis. It is now proposed by Dr. Héricourt to start with his serum injections again, having first vaccinated the dogs with the tuberculous birds.

The bacillus of tubercle, after having travelled through two or three of the animal kingdoms, ought to have its habits modified, and we trust it will satisfactorily affect the serum of the dog.

Alcoholic Injections for Cancer.—Dr. Schultz, of Buda-Pesth, reports ten cases of uterine cancer in which the disease was arrested by injections of alcohol. The patient is placed in Sims's position, a Sims speculum is introduced, and the meatus urinarius is guarded with wool lest it should be hurt by drops of alcohol falling on it. An instrument about five times the size of a hypodermic syringe, but otherwise similar, is employed. Five cubic centimetres of absolute alcohol are thrown up. The needle of the syringe should be passed about an inch into the cancerous tissues. This causes some pain, which, however, does not last long. The injections may be made daily or every other day, and the vagina should be packed with a strip of iodoform gauze after every injection. After about thirty applications of the syringe the cancerous tissue, in the cases under Dr. Schultz's treatment, almost disappeared, and epithelium grew over the eroded surface of the disease. How long this condition will last, observes Dr. Schultz at the end of one of his clinical reports, the future will show.

News of the Week.

The Practitioners' Society of New York celebrated its tenth anniversary, May 6th, by a dinner at the University Club. Dr. Peabody presided and acted as toastmaster. Speeches were made by Drs. W. M. Polk, C. L. Dana, George F. Shrady, A. A. Smith, Beverley Robinson, A. B. Ball, Robert Abbe, R. F. Weir, V. P. Gibney, and H. M. Biggs.

Castration as a Substitute for Capital Punishment.—Dr. H. A. Shelley writes to the *Medical News* regarding this subject: "Castration is not a *new substitute*, because it has been advocated since the year 1731 (*vide Medical Times and Gazette*, May 25, 1872). Dr. G. F. French, June 11, 1878, read before the Maine Medical Association a paper, entitled, 'The Eradication of Syphilis and Crime by the Extirpation, in that Class, of the Procreative Power.' Dr. Orpheus Evarts read before the Cincinnati Academy of Medicine, February 27, 1888, a concise, complete paper, entitled, 'Asexualization as a Penalty for Crime.'"

Abstracts were introduced into the United States Pharmacopœia of 1880 with a considerable expectation that a need was felt by the medical and pharmaceutical professions for just such a class of preparations. Up to this time the need has not been evident, and it might be well to consider the advisability of striking them from our official list.—DR. SQUIBB.

Application of the Sclerogenic Method to the Treatment of Ununited Fracture.—M. Ménard reported to the French Surgical Congress the cure of a case of ununited complicated fracture of the leg which had resisted the usual methods of complete immobilization for five months. M. Ménard injected into the insufficient callus 1 gramme 25 centigrammes of a ten per cent. solution of zinc chloride. From that moment consolidation made rapid progress, and in a month the patient began to walk. Here we have another success scored for the method devised by Professor Lannelongue.—*Lancet*.

Treatment of Rabies by an Intra-venous Modification of Pasteur's Method.—A highly important announcement has just been made by Professor Murri (*Riforma Medica*, April 13, 1892) with regard to the treatment of rabies. It appears that a man bitten by a rabid dog came for treatment to the Pasteur Institute at Bologna. Symptoms of paralytic rabies supervened, as sometimes occurs in certain individuals treated by Pasteur's method when the treatment does not suffice to neutralize the effects of the inoculation. The paralysis had already seized the patient from the waist downward, involving even the bladder and rectum, when Professor Murri and his assistants thought of trying the effect of intra-venous injections of the "virus fixe." As a result the alarming symptoms disappeared little by little, and now the patient is completely cured. Should the above result be confirmed on further experience, it will be readily admitted that a very great advance has been made in the treatment of rabies.—*British Medical Journal*.

One of the most Brilliant of Modern Novelists is Dr. Conan Doyle, an Edinburgh surgeon, who has, however, given up the art of medicine for the art of writing. One of his successful characters is that of an astute detective,

the prototype of whom was a Professor of Medicine at the University. This gentleman, we are told, would go into his patients' waiting-room with a face like a red Indian, and diagnose the people as they came in, before even they had opened their mouths He would tell them their symptoms, he would give them details of their lives, and he would hardly ever make a mistake. "Gentlemen," he would say to us students standing around, "I am not quite sure whether this man is a cork cutter or a slater. I observe a slight callus or hardening on one side of his forefinger, and a little thickening on the outside of his thumb, and that is a sure sign he is either one or the other."

Dr. Patrick McShane, Assistant-Surgeon of the Twenty-second New York Cavalry from August 30, 1864, to August 22, 1865, died in Bellevue Hospital of pneumonia, on Thursday, May 5th, at the age of seventy-four. He was born in Ireland and studied medicine in Rochester. His body lay unclaimed in the Morgue for two days.

A Curious Case is reported from the Chicago Pasteur Institute. An epileptic boy underwent a course of Pasteur treatment, on account of a dog-bite, in August, 1890. Since this he has had no more attacks of epilepsy.

Pathological Liars.—Dr. Bremer, of St. Louis, claims that there is a wide distinction between physiological and pathological liars. The physiological liar is one who lies to get out of a tight place, and a pathological liar is one who lies for the art of lying. Judging from their scurrilous reports anent physicians, Chicago reporters belong mostly to the pathological variety.

The Prospects of Medical Women.—Dr. Julia Mitchell has commenced in *Woman* a series of articles indicating "what women may do in the medical profession," commencing with their prospects and personal qualifications. "Everything," the writer thinks, "seems to point to a very brilliant future being in store for medical women," but not much is said as to how far such prospects are in course of being fulfilled for the rank and file. That women are born invalids, according to Michelet's theory, Dr. Julia Mitchell stigmatizes naturally enough as "all nonsense." But she admits it to be a curious fact, whatever may be the reason, that up to the present "women have shown no overwhelming desire to monopolize the accouchement branch of practice." She indicates it as a common mistake that women, once qualified, think they have only to put a brass plate on the door and patients will come flocking and guineas pour into their hands. There are good and well-paid posts in India open to women; but this lady remarks thereupon that the climate suits few, and she thinks that "the majority of the coming English lady doctors will prefer to stay at home and try their luck." She does not give any reassuring facts or statistics in support of her cheery opinion that the chances of medical women, especially in this gigantic and ever-growing city of London, are "very favorable." She thinks the medical Code "a wonderfully complicated and abstruse affair," but she warns her colleagues: "Woe to the man or woman who transgresses it!"

Tuberculin Again.—Two German physicians, Dr. Thorner and Dr. Aufrecht, have recently reported successful results from the use of tuberculin in tuberculosis. Both physicians began with extremely small doses. Dr. Thorner says: "No other method of treatment of bacillary phthisis, not excluding the climatic and that by creosote, can show such good results as Koch's method. Certain cases of tuberculosis first treated by tuberculin improve later on with creosote."

The Woman's Hospital.—The Aldermen have agreed, on certain conditions, to let the Woman's Hospital sell the block the hospital stands on, bounded by Fourth Avenue, Forty-ninth Street, Lexington Avenue, and Fiftieth Street. One of the conditions is that fifty free beds be assigned in the hospital for the use of invalids recommended by the Aldermen. The new hospital property, which is to be paid for with the proceeds of the sale of the old, will be held on much the same terms as the old site, and cannot be disposed of except with the city's consent. It is said that the New York Central & Hudson River Railroad Company have offered the trustees nearly $1,000,000 for the plot, and that the new site, which the trustees wish to purchase in the annexed district, can be had for $300,000. Originally the city gave the present site to the hospital for $1.

Blisters and Sinapisms.—Dr. L. Devoto, in an interesting contribution to the *Gazzetta degli Ospetali*, shares Dr. Besson's conclusions as to the therapeutic value of "intense and rapid revulsion"—sinapisms, that is to say, in contra-distinction to vesicants, which represent the group of revulsants "permanent and slow." The former he finds useful in acute disease by their power of lowering the temperature, of slowing the heart's action, and of producing a general vascular dilatation. In chronic disease where is encountered a falling off of nutrition, "cutaneous excitation has the power of determining an acceleration of organic combustion," besides exercising a calmative effect, more or less enduring, more or less considerable, on the phenomenon of pain. In syncope, moreover, they re-establish pressure and arouse the cardiac function. As to the slow and feeble revulsion, of which the vesicant is nowadays almost the sole representative, Dr. Devoto's experience harmonizes with that of Dr. Besson, for whom vesicants have but one indication—that of inducing anæmia of the subjacent tissue and relieving pain. In pneumonia their use is invariably negative, or worse. They have no power over the pulmonary lesions or over its morbid symptoms. "They augment the hyperæmia, they favor the dyspnœa and hypostasis, they predispose to asphyxia, and while suppressing, it is true, the pain at a given point, they reproduce it at another." Not less useless has he found them in pleurisy, while in diabetes mellitus, he considers, they are absolutely contra-indicated, equally so in aged subjects, in children, and, generally speaking, in all maladies the characteristic note of which is failure or feebleness of the powers.

Laparotomy on the Human Ostrich.—A person known to Dime Museum-land as "the Human Ostrich," has been swallowing tacks, glass, nails, etc., for the past eight years. He was recently admitted to the St. Louis City Hospital, where laparotomy was performed. The stomach was found to contain fully a pound of shingle-nails, sharp-pointed tacks, several screws, and a number of bits of broken glass, evidently of lamp-chimneys or very thin

tumblers. One miscellaneous bunch of shingle-nails and tacks was tied with a white cotton thread, and had evidently been taken at one dose. Kennedy is twenty-one years of age. He said that the Bellevue Medical College had made him a standing offer to pay $5,000 for his body whenever he should die, so firmly did the college authorities believe that his stomach was unlike that of other persons. Dr. Marks, the Superintendent of the St. Louis City Hospital, stated, however, that it differed in nowise from the normal.—*Weekly Medical Review.*

Constipation of Infants.—Karnitzky's method of treatment by abdominal massage was used by him in twelve cases of chronic and twelve cases of acute constipation in children from eight to eleven years of age. The following are his conclusions: 1. Abdominal massage may produce effects upon the alimentary tract, in connection with digestion, which are not inferior to those produced by purgatives. 2. Habitual constipation may be easily cured by massage without the aid of purgatives. 3. The younger a child is, the more readily can the constipation be cured. 4. The younger a child is, the milder should the manipulations be, and the shorter the *séances*. 5. The duration of the *séances* should be from three to ten minutes, according to the age of the patient. Longer *séances* are inadvisable, and may even be harmful and aggravate the condition of the patient. 6. Abdominal massage may be regarded as the best means of treating constipation in children. Purgatives should only be used in exceptional cases.

A Monument to Louis XIII.'s Physician.—A committee has been formed, under the presidency of M. Jules Clarétie, for the erection of a statue of Théophraste Renaudot, who was physician to Louis XIII. In addition to his professional claims to be remembered, Renaudot was the founder of modern journalism, and it is therefore only natural to find on the committee the names of the leading pressmen of Paris side by side with those of such representative members of the medical profession as Professors Brouardel, Charcot, Cornil, and Laboulbène. Renaudot is also believed to have been the founder of gratuitous consultations, and as such may perhaps be not unjustly considered the father of the out-patient system, which, in the eyes of many members of the profession, may constitute a more questionable title to fame than those first mentioned.

The Cholera in Paris.—It is rumored that cholera has appeared in Paris; but investigations so far make it probable that it is only a "scare."

Italy receives an annual income of about $50,000,000 from invalids and guests.

Jubilees of Two German Professors.—Professor Leyden, of Berlin, who was one of the physicians in attendance on the late Emperor Frederick during the last months of his illness, celebrated his sixty first birthday on April 20th. On the same day Professor Thiersch completed his seventieth year, and the twenty-fifth year of his occupancy of the chair of surgery in the University of Leipzig. This interesting "double event" is to be celebrated in the ceremonial fashion dear to the German heart on May 7th, when a marble bust of the Professor and an illuminated congratulatory address will be presented to the distinguished surgeon at his house.

A Physicians' Bureau of Service and Information at the World's Fair.—A Bureau of Service and Information, for the exclusive use and benefit of visiting physicians and surgeons and their families, with ample room for the successful operation of each department, and additional space for the use of the secretaries and other officers of medical societies and conventions, will be established at the Columbian Exposition by Charles Truax, Greene & Co., of Chicago. A list of leading hotels and boarding-houses will be kept, with location, description, and rates. A miniature post-office will be established, so that mail matter may be addressed to the bureau, and also telegrams. Telegraph, telephone, stenographic, district messenger, livery, cab, express, baggage, and freight service may be arranged for in the building, and legitimate rates secured. Parcels and small packages will be received and checks issued for the same. A reading and reception-room, with writing facilities and stationery, will be provided, where physicians may meet their friends, attend to correspondence, etc. Theatre, exposition, sleeping-car, and railway tickets will be secured, and assistance rendered in purchasing goods in all lines of trade. German, French, Spanish, and other interpreters will be permanently located in the building.

Dr. John Van Bibber, of Baltimore, a well-known specialist in nervous diseases, died recently, aged forty-two.

Presentation of Portraits of Dr. Oliver Wendell Holmes and Dr. Alfred Stillé to the College of Physicians of Philadelphia.—A notable occasion in recent medical annals was the presentation of a portrait of Dr. Alfred Stillé, ex-President of the Philadelphia College of Physicians, and one of Dr. Oliver Wendell Holmes, an Associate Fellow, to that body. The former, the gift of the physicians of Philadelphia, was presented through Dr. H. C. Wood, and accepted on behalf of the Fellows by the President; the latter, the personal gift of the President, Dr. S. Weir Mitchell, was accepted by the Vice-President, Dr. J. M. DaCosta. The occasion was a dinner of the College of Physicians of Philadelphia, on the evening of the 30th ult., at which were present, besides the Fellows, a number of Associates and invited guests, including Drs. William H. Welch, of Baltimore; Herman Knapp, of New York; William Osler, of Baltimore, and Talcott Williams, Esq., the entire number of those who sat down to dinner being nearly two hundred.

Dr. Charles F. Stillman, formerly of this city, died at Plainfield, N. J., on May 1st. The story of his career is a painful one. As many of our readers know, he was at one time one of the most promising and popular of the younger surgeons of this city. Two or three years ago he became involved in a domestic scandal, and left this city for Chicago. He followed his profession there, but was attacked with phthisis and came home at last to die. He was a man of large frame and robust physique, and the last person one would expect to be attacked with tubercular disease.

The Chicago Pathological Society has a lady president, Dr. Eliza H. Root.

The Measles Bacillus has been discovered, it is stated, by Dr. Canon, of Berlin.

Society Reports.

AMERICAN PEDIATRIC ASSOCIATION.

Fourth Annual Meeting, held at Boston, Mass., May 2, 3, and 4, 1892.

FIRST DAY, MONDAY, MAY 2D.

The Present Condition of Medical Research.—THE meeting was called to order by WILLIAM OSLER, M.D., of Baltimore. Dr. Osler reviewed the general condition of medicine of to-day and urged the necessity of continuing as heretofore from special branches; he also reviewed and praised the good work done by this Society, and the benefits derived from exchanging views from time to time. He also made a point worthy of mention by saying that in wealthy families who had a surgeon, a gynecologist, a dermatologist, an ophthalmologist, and laryngologist, there remained nothing for the general so-called family physician but the treatment of the diseases of children; this refers to practitioners chiefly in the larger cities.

Experiments as to the Value of Nascent Ozone in Certain Forms of Diseases of Children, with Demonstrations of an Efficient Generator.—This was the title of a paper read by DR. AUGUSTUS CAILLÉ, of New York. This apparatus was first shown at the Congress for the study of tuberculosis at Paris, in 1891, by Messrs. Labbé and Oudin. They claimed: 1. Increased metabolism in consequence of the high oxidizing power of ozone. 2. Destruction of the tubercle bacillus in the tissues in consequence of its oxidizing power and extreme diffusibility and ability to reach directly and indirectly the foci of disease in the lung. He treated three cases of tuberculosis, eleven cases of anæmia and chlorosis, and seven cases of pertussis with ozone, noting increase in weight and appetite, vital capacity, and increase in percentage of oxyhæmoglobin, and came to the following conclusions: 1. Inhalations of ozone by means of Labbé and Oudin's apparatus, have not been followed by noticeable ill effects. 2. Daily inhalations of ozone increase the quantity of oxyhæmoglobin in the blood from one to four per cent. in a short time, and this increase remains stationary for some time.

In three typical cases of limited apex tuberculosis, local improvement was not obtained.

In pertussis, ozone inhalations have a very distinct curative effect as regards duration and severity of the disease. In chlorosis and anæmia, ozone inhalations are exceedingly valuable, and give better and prompter results than any other form of medication.

DR. EMMET HOLT wished to know in what stage of the pertussis the treatment was commenced.

DR. CAILLÉ answered when paroxysms were most marked and spasms distinct.

DR. ROTCH thought good work could be done, and possibly pernicious anæmia avoided, by a careful examination of their blood.

DR. NORTHRUP asked if ozone had ever been used in purpura.

DR. CAILLÉ answered negatively, but stated that he very much desired to try it in a case of purpura.

DR. A. JACOBI said he had a case of scurvy which he will submit to Dr. Caillé for experimental treatment.

DR. BLACKADER, of Montreal, asked, is there any immediate effect on the heart of patient.

DR. CAILLÉ answered that he had noticed a slow pulse, but no other distinct heart-action.

DR. LOUIS FISCHER stated that he had examined a large number of cases of anæmia, and he had carefully examined sputa of patients sent to him by Dr. Hilgard Tyndale, of New York; that they were suffering from apparent anæmia and really suffered from a pretubercular condition; that the presence of tubercle bacilli made the diagnosis positive. He then asked Dr. Caillé if, in the cases of anæmia and chlorosis mentioned as benefited or cured, he had had excretions, as sputa, examined for bacilli.

DR. CAILLÉ replied negatively.

Manifestations of La Grippe in Children.—This was the title of a paper read by DR. CHARLES WARRINGTON EARLE, of Chicago, Ill. He called grippe a national calamity; he dwelt on the fact that influenza was contagious, and cited examples where a mother in puerperium had infected her nursling, although the period of incubation had varied from a few days to a few weeks. The period of incubation was sometimes very long and sometimes very short. Immunity was rare. There were two symptoms which he had noticed which were not recorded by others: 1. Subnormal temperature, sometimes as low as 93° F., in axilla. 2. Loss of body-weight. These were especially marked in the epidemic of 1891.

DR. ROTCH'S experience differed entirely from Dr. Earle's, and might probably be because the disease is more severe in the West. The same was said about typhoid fever by Dr. Vaughn, in a discussion some few years ago. Dr. Vaughn maintained that typhoid was severer in the West than in the East. The same seemed to be true about the severity of influenza. He concluded by asking if any autopsies had been made.

DR. EARLE replied negatively.

DR. ROTCH believed, and this he made his strongest point, that the infection of influenza affects the sympathetic nervous system; which must be demonstrated, however, more clearly in the future.

DR. A. JACOBI believed, as in a paper read before the New York Academy of Medicine, that influenza could be divided into three forms: 1, Gastric; 2, respiratory; 3, nervous. He disagreed with Dr. Earle in many respects. Dr. Earle maintained that the infection in influenza is brought about by the bacillus generating a toxine, as the diphtheria bacillus generates a toxine and thus affects the general system. Dr. Jacobi did not believe this.

DR. CAILLÉ next called attention to a peculiar cough, resembling a reflex cough, like pertussis in influenza, which he found only in grippe cases.

DR. HUBER said that, although the surface temperature might be lower, he believed that a rectal temperature would show the true state of affairs.

DR. L. EMMET HOLT had not seen such serious cases as those here described by Dr. Earle. He saw about thirty to forty cases of pneumonia in the New York Infant Asylum, and believed that as they were very fatal, there might be some causal connection between influenza and the serous pneumonia. He had, however, never seen the low temperatures described by Dr. Earle, but on the contrary, always high ones.

DR. ADAMS, of Washington, said that he believed the climatic relationship had a great bearing on the kind, *i.e.*, mild or severe form, of influenza developed.

DR. BLACKADER, of Montreal, next spoke. He had noticed the peculiar cough mentioned a moment ago by Dr. Caillé in pertussis cases. He had never yet encountered a fatal case of influenza. He has had deaths from pneumonia, but none distinctly from la grippe.

DR. BOOKER, of Baltimore, had good results from boracic acid in the treatment of cough (reflex) in the naso pharynx.

DR. EARLE closed the discussion by stating that he had had severer cases of vomiting and diarrhœa in children in midwinter than he had in summer in cholera infantum from bottle-fed babies; that he attributed this purely to the effects of the poison of influenza.

An Epidemic of Alopecia in a School of Girls.—DR. CHARLES R. PUTNAM, of Boston, read a paper with above title. He demonstrated three cases of alopecia areata. Treatment consisted in cutting their hair short and using cantharidine ointment; in some he used bichloride of mercury, 1 to 2,000, and bichloride of mercury, 1 to 1,000. Although he believed the disease due to infection

from a micro-organism, none could be found by a careful microscopical examination.

Dr. Bove examined sixty-three cases with care microscopically, never found germs nor spores.

Dr. White closed the discussion by saying he examined five or six of these cases. They seemed to differ from ordinary alopecia areata, and still he must call them so. They differed not in surface appearance, but the outlines of the spots were more angular.

Dr. A. Jacobi asked if hair that grew came out white. This was answered negatively, and the session adjourned for the day.

Second Day, Tuesday, May 3d—Morning Session.

The meeting was called to order at 10 A.M. Dr. Osler, of Baltimore, President, in the Chair.

Hydrorachis and Hydrocephalus, with Demonstration of a Carefully Prepared and Highly Interesting Specimen.—Dr. A. Jacobi, of New York, read a paper with the above title. He believed that as to injections and punctures there was little, if any, reaction, though there was a complicating disease; no vomiting, except once when there was a gastro-intestinal complication. The infant always cried during injection of an iodine solution, and quieted down within a minute after the needle was removed. Only once an ice-bag appeared to be required.

Puncture of head was tolerated without pain or uneasiness; it had no influence in diminishing the effusion; on the contrary, within a week the measurements pointing to lateral ventricle increased. It appears that without any more symptoms, the rapid effusion following the puncture may assume an inflammatory character, for the albumin increased from $\frac{1}{8}$ to $\frac{5}{10}$ per cent. within one week.

Lower Extremities: Fœtal luxation forward and upward must have taken place at an early period, for the acetabulum is filled out, indeed has lost its shape, if ever it had it. Head of femur is also abnormal. Can it be explained by insufficient or abnormal innervation? Hardly, for the muscles of the thighs are normally developed, and we do not know of any muscular traction that could tear the head out of its socket. Which, then, was the power resulting in bilateral luxation? Was it the result of early aphasia? The bone material of the vertebral column was not sufficient.

While the muscles, etc., of the thighs appear well developed, the legs are atrophied, and both feet are clubbed. It is noteworthy that the peripherous ends suffer to such an extent. This is exactly as it is in most cases of poliomyelitis of the normal infant or child. But in our case the muscles are all atrophied, extensors and flexors, while in poliomyelitis the extensors are mostly or exclusively affected. This extensor paralysis is the cause of paralytic club-foot in poliomyelitis. In our case the cause of club-foot must result from another cause, inasmuch as all the antagonists of both sides are affected, and no predominance of any one set of muscles can be suspected. I have to emphasize this point, because club-foot is a frequent occurrence in most forms of special meningocele and myelocele. I look for the cause of both the congenital luxation of the femora and the bilateral club-foot in the influence of external pressure. The mother, who had several normal children before, noticed the difference between the sizes of her abdomen during her pregnancy. There was but a small amount of liquor amnii. From the first the fœtal extremities had no space to swim in and were pressed in one direction, that one direction was but the exaggeration of the normal position of the fœtus in utero. I do not know whether this causation is acknowledged in obstetrics and pathological anatomy, but when I proposed it years ago, in reference to many forms of club-foot alone, before a society of surgeons, it met with approval. If so, in our case both the congenital luxation and the club-foot would be a complication of the hydrorachis, and not its result. Unless any other theory might be suggested, which would be that the defect in bone material, as perhaps evidenced in the lower part of the vertebral column, was equally visible in the formation of the neighboring pelvis.

Dr. Emmet Holt, of New York, stated that he made an autopsy on a child aged five months, wherein considerable fluid had been removed during life. His experience was not encouraging. He asked Dr. Jacobi if he found or knew of success to follow the operation for hydrocephalus.

Dr. Jacobi answered negatively, adding, however, that although some cases had been reported which claimed to have been cured, that these cases were, in his opinion, not long enough under observation to give a decided report, although (he humorously added), if an injury by a horn of a cow might perforate a cranium and thus allow fluid to escape, he did not see why an aseptic knife might not cause the same effect and possibly benefit.

Dr. Osler stated that Dr. Quincke had operated but with apparent success.

Dr. Koplik stated that a good surgeon in New York had operated, but after puncturing the cavity had refilled, and both his cases proved fatal. One case had convulsions and suddenly developed opisthotonos, although puncture was early.

Dr. Caillé, of New York, looked upon the operation for spina bifida as of no avail, because the malnutrition would interfere with otherwise good results. He had reported two cases in which the cyst got smaller.

Dr. Northrup, of New York, said it seemed to him that the prognosis was very unfavorable, as the post-mortem examinations of cases seen by him showed considerable dilatation of the ventricles in the brain.

Dr. A. Jacobi closed the discussion.

"Nomenclature of Diseases of the Mouth," by Dr. T. M. Rotch, of Boston, was omitted because the Committee on Nomenclature of Stomatitis postponed its report.

Pseudo-Diphtheritic Processes was the title of the next paper, read by Dr. W. D. Booker, of Baltimore. It was an extensive paper with considerable experimentation, but nothing especially new. The author confirmed the views and reports of a series of investigators, and finally demonstrated two agar specimens of staphylococcus and one of diphtheria. He devoted his investigations to the pathological anatomy and clinical observations, rather than to a distinct bacteriological investigation.

Forms of Diphtheria which Simulate Simple Angina.—Dr. Koplik, of New York, read the above paper. He announced his methods of carefully arriving at a diagnosis by a bacteriological examination, and showed several photographs of cultures with the pseudo-diphtheria bacillus, and also with the true diphtheria bacillus. He reported an important clinical observation of a few children having apparent mild forms of angina, which by a culture proved to be the virulent form of diphtheria. He had used animal experimentation, and was pleased with his results. He also referred to valuable assistance which he had received from the Carnegie Laboratory in New York. He also showed some neatly executed micro photographs of pure culture of diphtheria bacilli and involution forms, and also some of the pseudo-diphtheria bacillus. He was greatly impressed by the recent publication of Baginsky, in Berlin.

Dr. F. Huber, of New York, next presented two well-formed specimens of bronchial casts which he had received, one from a case wherein he found it necessary to perform tracheotomy.

Dr. J. Lewis Smith expressed by letter his regret at his inability to attend the meeting, owing to an attack of laryngitis. Dr. Dillon Brown, of New York, was also reported absent.

Dr. Caille opened the discussion by saying that he also had seen casts expelled after tracheotomy and was delighted to see the fine specimens of Dr. Francis Huber. Continuing, he said, in discussing Dr. Koplik's paper, that it was folly to try to discard clinical observa-

tions for bacteriological investigations. He summed up by saying that the main point was to decide at the bed-side of the patient whether we had a case of diphtheria or not.

Dr. Louis Fischer, of New York, commenting on Dr. Koplik's paper, said that while at Berlin last summer he had, under the tutorship and kindness of Dr. Baginsky, made a considerable number of investigations which he pursued at the Hygienic Institute at Berlin, and finally completely embodied them in experiments performed at the laboratory of the New York Hospital. These were carefully prepared and read before a medical society, and published in extenso in the New York Medical Record. Editorials were printed in the *Medical Age*, in Detroit, and also in the *University Medical Magazine*, in Philadelphia. He believed that it was easy, with proper precautions, to make a diagnosis with the aid of certain trifling instruments, as, for example, a long-toothed forceps properly sterilized and a few agar (glycerine) tubes. All that was required at the bed-side was to snip off a piece of supposed diphtheritic membrane, and these tubes, after being inoculated, could be laid in the thermostat, even a few hours after carrying about, without injuring the virulence of the bacillus of diphtheria.

Dr. Seibert, of New York, next asked Dr. Louis Fischer what he proposed to do in diphtheria while waiting for the guinea-pigs to die.

Dr. Fischer: Use all symptomatic treatment to counteract any serious symptom, and put the child on expectant plan of treatment; this usually did not take more than about one-half or three-quarters of a day.

Dr. A. Jacobi maintained that the stronghold in doubtful cases, be they diphtheria or not, was in isolation. He knew of many physicians who would run risks of allowing children mildly affected with diphtheria to wander about and so become dangerous to others. He knew of some who merely called those cases ending fatally, diphtheritic; cases which got well, non-diphtheritic. He furthermore impressed upon his hearers that in many cases of angina a probe could be carried into the follicle, whereas in diphtheria this is not the case. He concluded his remarks by expressing the hope that bacteriologists would find a method by which, as at present with the bacillus tuberculosis, a child could be instantly and positively examined, so that a bacteriological examination capable of being executed at the bedside by every practioner should soon loom up, and draw the line between what is and what is not diphtheria.

Afternoon Session.

Meeting called to order by Dr. A. Jacobi, of New York.

Typhoid Fever in Children under Two Years.—Dr. Northrup, of New York, read a paper with this title. He stated that he had made about two thousand autopsies, and among these he saw about one hundred and fifty cases of enlarged glands not ulcerated. This enlargement was what excited his suspicion. He furthermore believed that an enlarged spleen cannot be percussed and palpated unless it is pushed below the ribs by crowding.

A long discussion followed, which was participated in by Drs. Koplik, Huber, and Winters, of New York, Blackader, of Montreal, and others.

Cold irrigations were mentioned by Drs. Rotch and Seibert as useful, although Seibert had seen a very large hemorrhage, probably through laceration of an ulcer in the colon.

Dr. Blackader believed the reason that children were not as frequently affected as adults was because they ate and drank fluids, most of which are boiled and therefore sterilized.

The discussion was closed by Dr. A. Jacobi.

Typhoid Fever in Children.—Then followed a paper on this subject by Dr. Charles Warrington Earle, of Chicago, Ill.—The author prefaced his remarks by alluding to the exaggerated, dangerous reports of the *British Medical Journal*, and dwelt at some length upon a recent editorial in the Medical Record, entitled a "Warning to Chicago." He hoped somebody would quiet Dr. Shrady, in New York, as the dangers from contaminated water were groundless, and stated that the water in Chicago is exactly identical with that in Vienna. He then described certain peculiar symptoms noticeable in the course of typhoid fever at Chicago, and stated that one child sang first "Annie Rooney," and "Jesus, lover of my soul."

He finally concluded by urging two points: 1 That children must be kept at least four days in bed with absolute rest after the temperature has entirely subsided. 2. A fluid diet, and fluid diet only. He had seen cases relapse after allowing solid food. He had frequently allowed himself to be influenced by patients and gave them solid food, with invariably disastrous results.

Typhoid Fever in Infancy, by Dr. W. S. Christopher, of Chicago, was the title of the next paper read. Owing to absence of the author the paper was read by Dr. Perry Watson. A point strongly brought out in this paper was that bronchitis usually accompanies typhoid. The tongue is not indented by the teeth as in adults. The tip is bright-red and always moist. Face does not have typical anxious expression. The spleen he found always enlarged.

Dr. Joseph Winters, of New York, in discussion, said he could not recall one single case of typhoid under two years.

Dr. Huber had seen several cases at the clinic of Dr. Jacobi, in New York. The diagnosis of gastro-enteritis had been previously made, and only after distinct symptoms were later on pointed out by Professor Jacobi, was the diagnosis of typhoid fever made.

Dr. Adams, of Washington, believed that change of air was very beneficial in the treatment of the disease.

Dr. Northrup asked Dr. Huber if he could percuss and positively map out a spleen.

Dr. Huber replied negatively.

Dr. Rotch believed, as it was not an ulceration, we do not get perforation. He believed the diagnosis would have to be made by exclusion. He believed as the pathological changes were mild, the symptoms were accordingly mild.

Dr. A. Jacobi said he had a report of 25 cases with him: of these there was diarrhœa in 15, constipation in 6, epistaxis in 6, spleen felt in 16. He observed the roseola between the fifth and tenth day of the disease in 14 of above cases. The mortality was twenty per cent. He firmly believed he had seen a case of typhoid in a baby of three weeks.

The positive signs of diagnosis in typhoid are: 1, A double curve of temperature; 2, if child can bear a temperature of 106° F., and soon after play; 3, when roseola is present; 4, when spleen is enlarged; 5, diazo reaction (urine) described by Professor Ehrlich, of Berlin.

The next paper, by Dr. Forchheimer, "Acute Emphysema in Children," was omitted, owing to author's absence.

Pretubercular Anæmia, by Dr. B. K. Rochford, of Newport, Ky., was next read. He described one hundred and sixty-six cases of carefully observed patients in a convent. He had dwelt upon the amounts of hæmoglobin present in these cases and their influence.

He described the good results of iron in their treatment, and watched microscopically the gain in strength of the red blood-corpuscles. He believed that many of these cases of anæmia were early manifestations of a latent tuberculosis.

Dr. Fischer, in discussing the above paper, urged again what he had said yesterday while discussing Dr. Caillé's paper. He fully agreed with the author that many cases of anæmia and chlorosis were nothing else than a modified or latent form of tuberculosis; and in a case of anæmia with nothing else than an occasional

diarrhœa—and no pulmonary symptoms—the bacillus tuberculosis had been found in the stools.

On motion of Dr. Rotch a vote of thanks was extended the author, for the excellence of his paper.

Sporadic Congenital Cretinism was the title of the last paper for the day, and was read by Dr. Charles N. Townsend, of Boston.

A very clear description of a cretin and also its photograph were presented.

In the discussion which followed it was proven that, in New York, Dr Huber had seen several cases, whereas Dr. Earle, of Chicago, had never seen a case and for this reason might call on New York.

Dr. Rotch stated that he had reported a paper eight years ago, drawing parallels between the bones of 1, case of cretinism; 2, rachitis; 3, syphilis, with a demonstration of these bones.

Dr. Osler had looked through the literature and could find but one case in American literature, this case in Massachusetts. He had heard of a case of cretinism in Canada, and while driving there called on this patient, and was disappointed in finding a dwarf rachitis.

(To be continued.)

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

LIGATURE OF SUBCLAVIAN FOR AXILLARY ANEURISM—DISCUSSION ON PSILOSIS—THE PRESIDENCY OF THE ROYAL COLLEGE OF PHYSICIANS—HEREDITY IN THE MEDICAL PROFESSION.

London, April 26, 1892.

At the last meeting of the Medical and Chirurgical Society Mr. Rickman Godlee read a paper in which he gave an account of a case of axillary aneurism in which he ligatured the second part of the subclavian artery. The aneurism was on the left side and was a large one; the left subclavian was dilated, and there were signs of pressure on the brachial plexus. Tufnell's treatment was tried for three weeks, but without effect, and the aneurism appeared to be increasing in size. The left subclavian was then tied with catgut in its second part. The wound healed by first intention and the aneurism contracted slowly, but the patient complained of pain in the upper arm.

Dr. George Thin then read a paper on "The Symptoms and Pathology of Psilosis—Linguæ et Intestini." He described two typical cases and contrasted them with cases of tropical diarrhœa. In the acute condition the motions were pale yellow and liquid, but when the diarrhœa had ceased and the motions had become solid the patient passed—usually once daily—a large formed white stool. Dr. Thin adduced clinical evidence, and that of a post-mortem examination in a previously published case, to show that these white stools were coincident with a normally healthy condition of the liver and pancreas. Dr. Wethered had found that the large, creamy, soft masses passed from the bowel consisted of almost pure cultivations of bacteria, a rod-shaped bacterium of moderate and definite size largely predominating over the other organisms present. Analysis of the fæces in one case showed that half of the organic solids contained in them consisted of neutral fats, apparently milk-fat (the patient was on a pure milk diet), which had passed without being digested. Dr. Thin referred to a paper by Drs. Allan Macfadyen, M. Nencke, and M Nieber, in which it was shown (by observations in a case of fistula near the ileo-cæcal valve) that the food-mass which passed into the colon was acid, while the mucosa of the ileum was alkaline, and both the mucosa and the contents of the large bowel were alkaline. He believed that in psilosis the alkaline secretion of the mucosa of the ileum was wanting, that the food mass that passed into the large bowel was more than usually acid, and that the fæces were acid. He suggested that the abnormal reactions must produce abnormalities in the development of the bacteria normally present in the bowel, and that, under the influence of abnormal bacterial products, the normal coloring matter of the fæces was either not formed or was destroyed. The same condition, but to a less marked extent, obtained in some cases of ordinary tropical diarrhœa. He considered it an established clinical fact that persistent white stools might be passed while both the liver and pancreas were healthy.

Dr. Eccles referred to the reaction of the intestinal contents, and described some experiments which he had made with salol. This substance was quite insoluble in acid liquids, but perfectly soluble in alkaline ones. It ordinarily appeared in the urine forty-five minutes after ingestion, but in cases of psilosis or sprue, so long as diarrhœa was present, salol could not be detected in the urine till thirteen and a half hours after ingestion. This showed that the intestinal contents were acid. As the diarrhœa subsided the salol could be detected after a shorter interval, and in one case of recovery he had found it fifty minutes after ingestion. The disease could remain latent in the system for a remarkably long time; he had seen cases in which it had reappeared for the first time three to seven years after the patient had returned to this country. It could be successfully treated by a purely milk diet.

Dr. Manson said sprue might be an idiopathic disease, but was generally superadded to some disease of the lower bowel. It occasionally existed without the lower bowel being implicated, and was often present for months before the onset of the diarrhœa. The peculiar raw state of the tongue was pathognomonic of the disease. It was the most common and the most fatal of the serious tropical diseases.

Dr. Johnstone said protracted residence in malarial districts had much to do with the causation of the disease and urged that change of climate was essential for its treatment and was nearly always successful in the early stages.

Dr. Thin, in reply, said he had come across cases of psilosis in which there was no malaria coexisting. He thought the disease was distinct from "hill" diarrhœa.

Sir Andrew Clark has been re-elected as president of the Royal College of Physicians. The coming year will be the fifth during which he has held the office. It is customary to re-elect the president for a few years, and Sir William Jenner even held the office for seven years. At the College of Surgeons re-election is exceptional, and within recent years Sir William Savory was the only president who served several years. Another marked difference between the two colleges in regard to their presidents is as to the manner of election. At the College of Physicians all the Fellows have a vote in electing the president; at the Surgical College the Council elect one of their own body.

It is somewhat remarkable that of those medical men who have achieved distinguished positions few have sons who follow the profession of their fathers, and in still fewer cases do the sons achieve any position at all comparable with that of their fathers. There are numerous exceptions, of course, but these only confirm the rule. In the case of general practitioners it is more usual than otherwise for a son to adopt his father's profession, and there are country practices which have been in the same family for nearly a hundred years. In consulting practice the rule is the other way, and it looks as if the qualities which go to make up a successful consultant were not to a large extent the result of heredity. Take, for example, our nine living medical baronets. Only three of them have sons who are medical men, and in only one case is it the eldest son; this exception is in the case of Sir Andrew Clark's eldest son, who is an army surgeon. Sir Henry Acland and Sir James Paget have each a younger son in the profession. Sir William Jenner has a younger son now studying medicine, but his eldest son is a cavalry

officer. Sir William Savory's son is a clergyman. Turning to the sons of deceased medical baronets, we find that the eldest sons of Sir Thomas Watson, Sir William Gull, and Sir William Bowman were all members of the legal profession.

OUR BERLIN LETTER.

(From our Special Correspondent.)

THE BACILLUS OF MEASLES—IMMUNITY STUDIES OF BRIEGER. KITASATO, AND WASSERMANN.

BERLIN, April 18, 1892.

WHOEVER will, in future history, describe medicine in the nineteenth century, can rightly call the present epoch the bacteriological era. In reality we find among the acute infectious diseases so many unsolved problems, that this field for work certainly deserves the amount of sweat which earnest workers cause in its behalf.

The discovery of the bacillus of influenza is followed by the discovery of the bacillus of measles.

Drs. Canon and Pielicke, assistants to the general hospital Moabit, have, in the latest number of the *Berlin klin. Wochenschrift*, published an account of the above from which I extract the most important points. The bacilli were found in the blood of fourteen consecutive cases. They stain, as is the case with the influenza bacillus, with eosin and methylin blue. But only the latter staining methods are of use; for example, Gram method of staining proved negative. By the treatment of eosin-methylin blue, the measles bacilli appear with blue stain. Sometimes the staining appears uniform throughout the whole of the bacillus, sometimes the centre of the bacillus is paler, and the end poles of the bacilli intenser in staining. Sometimes only the borders of the bacilli take on the stain. The size of the bacillus is different, they sometimes appearing about one-half of the diameter of a red blood-corpuscle, other times, small bacilli appear which resemble doubled micrococci; between these there are intermediate forms. Frequently they appear broader than long, or *vice versa*, so that they resemble a double bacillus, or a bacillus divided in its centre. Frequently the bacilli are slightly bent, especially in the blood during the latter stage of the disease. The number of bacilli found in the blood was never uniform, sometimes several specimens were examined until a single bacillus could be detected; again, a single microscopical field would show innumerable bacilli. They appeared singly, but usually in piles, or bundles, ranging from eight to twenty bacilli.

The bacilli were found during the whole course of the disease, the greatest number were found when the febrile process was over. The same bacilli were found in the nasal secretions, and secretions from the conjunctival mucous membranes, and also in sputum, if any. To prove the existence and development of the bacilli, cultures were made in the usual manner. There was a drop of blood taken from the point of a finger and inoculated for development on the usual culture media, *e.g.*, glycerine, agar, blood-serum, bouillon, and milk. The only place which by experiment proved successful was bouillon. In the latter the bacilli developed, but a further development of the bacilli from the bouillon was unsuccessful.

According to Canon and Pielicke, the bacilli found by them are totally different from any previously described micro-organisms. It is hardly necessary to reiterate that in the examination two important factors are wanting: 1, the clean culture; and 2, animal experiment. The first has not been successfully carried out, the second seems not to have been tried. The scepticism which has been thrown on the etiological importance of the discovery is therefore wholly justified. In this case the importance of the presence of the bacilli cannot be underestimated, and will probably cause future investigators to fill out the necessary factors to complete the investigation according to the standard of scientific research of to-day. Then, and then only will the question of diagnosis and therapeutics be successfully discussed.

Parallel with this bacterium-hunt there is an important topic, equally as important as the bacillus question, *i.e.*, the question of immunity, now being seriously considered.

Only recently, an important series of publications by Ehrlich, Behring, Buchner, Röhmer, Klewperer, Brieger, Kitasoto, and Wassermann, giving a highly scientific and important insight into future pathology. The above discoverers pursued the problem that, in animals we must find certain conditions or factors capable of neutralizing and destroying all toxic products produced in a normal condition. These antitoxic bodies, they assume, are to be found in the thymus gland and in the lymphatic system. In order to test the accuracy of their supposition, they secured the thymus gland of a calf and made an extract therefrom. This latter extract was procured by heating to 100° C. in a steam sterilizer, and pouring the fluid so received into sterilized test tubes. To the latter a strong pure culture was added. The result was surprising; for it was found a fourteen-day old growth of virulent tetanus bacillus was three to five thousand times weaker than the same strength of a bouillon culture.

In another mixture containing the double quantity of the thymus fluid, as in the peptone-bouillon culture, they could inoculate and protect rabbits against full virulent cultures of tetanus bacilli. The same success was found when mice were inoculated with a thymus tetanus mixture. Similar experiments were then commenced with diphtheria, typhus, swine erysipelas, and cholera.

With cholera it was found that a culture made on thymus extract of cholera culture proved, after a single heating to 65° C., to be almost poisonless in about eighty per cent. of all specimens tried.

In diphtheria the toxic properties and principles could be entirely neutralized by adding to a pure culture of diphtheria bacilli a mixture of thymus gland extracted as above.

In typhus the authors could, in the case of white mice and guinea-pigs, protect and render absolutely immune, by a single preventive treatment of a mixture of typhus-thymus culture heated to 60° C., against a full virulent culture of typhus. The blood-serum of these animals could protect other animals against the disease.

By experiments with swine erysipelas it was found necessary to combine thymus erysipelas culture with a weakened erysipelas culture in order to insure success.

Two mice which were inoculated with a deadly culture (killing within eight to ten days) of an erysipelas culture, and in which treatment was commenced twenty-four hours later by a thymus-erysipelas culture, entirely recovered.

Four other mice infected as the above two, but without the latter antitoxic treatment, all died.

Prophylaxis of Malaria.—At Blantyre, a Scottish settlement and mission near Lake Nyasa, in Central Africa, there is published a little paper called *Mission Life and Work*. In an article referring to the ravages of malarial fevers along the common routes of travel—almost wholly by water-ways—the following statement is made: "Twelve grains of quinine with five drops of eucalyptus oil have been taken every third day during a journey lasting three weeks, from Quilimane, at the mouth of the Zambesi, up into the Lake Country; no fever developed at that time or since." The writer believes that the immunity was obtained by this combination of the oil of eucalyptus with quinine, taken at regular intervals. As an antimalarial combination, in districts where quinine alone does not suffice, this suggestion seems worthy of trial precisely as proposed.—*Journal of the American Medical Association.*

The Latest Thing in Spittoons for consumptives is a pocket arrangement, made of cardboard, in the shape of a cigar-case. The cost of it is only about three and one-half cents, and it is intended to be burned when full.

THE SANITARY CONDITIONS OF CHICAGO.

To the Editor of the Medical Record.

Sir: Your editorial on the sanitary conditions of Chicago, printed in your issue of April 23d, is calculated to cause alarm in relation to a subject on which popular feeling is sensitive, and which at this time has more than a local interest in view of the multitudes from all nations soon to be drawn to the city by the opening of the World's Fair. On such an occasion it is only just that the public should know the truth. From an article on typhoid fever in Chicago, you quote this from the *Medical Press*: "The prevalence of the disease is attributable to the unsatisfactory condition of the water-supply of the place, which is at present drawn from the river." A more erroneous statement could not easily be made. The inlet to the tunnel under Lake Michigan through which Chicago now receives its water, is in deep water, two miles from the shore of the Lake. An extension of this tunnel is now nearly completed, and in a few months the water will enter the tunnel four miles from the shore. The sewers of the city empty into the Chicago River.

From Bridgeport, at the head of the river, its waters and sewage are pumped into the Illinois and Michigan Canal, through which they are finally carried by the Illinois and Mississippi Rivers to the Gulf of Mexico. Except when—at infrequent intervals—heavy rains cause floods in the river, or the pumps become temporarily disabled, the river does not empty into Lake Michigan. New pumps are now being erected at Bridgeport, and in a few weeks are expected to be in operation, and then we will be able to pump seventy-five thousand cubic feet per minute from the river into the canal, "which will change the body of the Chicago River twice every twenty-four hours, and absolutely remove all danger from sewage to our water-supply" This quotation is from a personal communication from Dr. Ware, our Commissioner of Health. I believe our percentage of deaths to population compares favorably with that of any other large city. This, however, will certainly be reduced, for nature has favored Chicago with exceptionally healthful surroundings. But no city can be built as rapidly as Chicago has been, and still maintain everything at all times in an ideal state of perfection.

There is no more wholesome water than that with which the Great Lakes, stretching from Duluth and Chicago to the St. Lawrence, are filled, and this Chicago will supply in abundance, pure and uncontaminated, both to her citizens and the strangers within her gates. If those who attend the World's Fair have no greater cause for fear than they will find in the air they breathe and the water they drink while here, they may count themselves happy. Are we not in an unnecessary frenzy of fear of germs and microbes, and all the "gay motes that people the sunbeams?" Since we know more about them, we are ready at every turn to exclaim with Hotspur, "'Tis dangerous to take a cold, to sleep, to drink."

Ephraim Ingals, M.D.

34 Throop Street, Chicago, Ill.

THE TREATMENT OF FAVUS.

To the Editor of the Medical Record.

Sir: In your issue of April 30th, Dr. Sheldon Guthrie Evans gives results of treatment of 150 cases of favus, with bichloride of mercury dissolved in alcohol, 1 to 500, and asks for statement of results, should anyone try the method, and that he has been unable to find this treatment in any books at his command. In the American Edition of Aitken's "Practice," published in Philadelphia in 1866, from the Fourth London Edition, the author states that Kuchenmeister frequently succeeded with alcohol.

Robin, and Bazin, are credited with recommending corrosive sublimate in solution, 1 to 500.

Epilation, or shaving the scalp, is deemed necessary by the author in all cases.

From these suggestions, I was in the habit, twelve or fourteen years ago—my experience being confined to infants—of simply cutting the hair moderately close, if there was enough to be in the way, and direct the crusts to be dissolved off by washing and rubbing lightly with a soft sponge, and a saturated solution of borax, or bicarbonate of soda, in soft water; care being taken not to detach the crusts, but to dissolve them. This is rarely accomplished for several days, but the crusts can be thinned very much at each washing. Then a thorough wetting of all the diseased skin with alcohol.

Later on, becoming more familiar with the use of corrosive sublimate in surgery, I have used it in these cases in strengths varying from 1 to 3,000, to 1 to 1,000 in distilled or soft water, abandoning the alcohol altogether, washing with the solution of borax or soda, morning and evening, applying the corrosive sublimate solution immediately after, and also at noon, avoiding all oily applications, lest they interfere with the medicated solution penetrating the hair-follicles. They get well in a very short time.

It is possible that after dissolving the crusts, a complete antiseptic dressing with moist bichloride gauze would be an improvement on the plan above described, but I never thought it would add to the comfort of my little patients, and the other is so very satisfactory, and can be conducted at home by the mother. I have no record of the number of cases treated, but have used only the bichloride solution for six or seven years, and in strength very much less than that recommended.

H. W. Chapman, M.D.

Whitehall, Ill.

THE ANCIENT HISTORY OF A NEW NEEDLE.

To the Editor of the Medical Record.

Sir: In your issue of April 30th Dr. George Place Clements, of New York, gives a description and cut of a new needle for silver-wire sutures in operation for lacerated perineum, etc., which he devised, and thanks are added for Mr. C. F. Ford for the interest of manufacturing the needle and carrying out the *idea* of the doctor.

But this needle is an invention of Dr. Alexander S. Stone, of St. Paul, of at least ten years' standing, used by him during this time, and for about six years by the writer, for the operation of lacerated perineum. As enclosed cut shows, the needle is manufactured by G. Tiemann & Co., and appears in the catalogue of this firm for many years. Respectfully yours,

H. Hahn, M.D.

St. Paul, Minn.

To the Editor of the Medical Record.

Sir: In the Medical Record for April 30, 1892, Dr. George P. Clements describes "a new surgical needle." In 1872, having seen for the first time a laparotomy, I devised an instrument similar to the one described by Dr. Clements, excepting that it was furnished with a milled wheel that materially assisted in forcing the wire through. I sent a drawing of my perforated needle to Messrs. Tiemann & Co., who returned it immediately and sent with it an instrument almost precisely similar to it, which they assured me they had had in stock for a number of years, and which, if I am not mistaken, was devised by the late Professor Edmund R. Peaslee. Possibly some of the older employees of Stohlman, Pfarre & Co. may remember such a wire-carrier. I trust that the discovery of this ancient instrument may not bring as much disappointment to your correspondent as it did to

Yours,

Vetus.

The Prescribed Course of medical instruction in the Mexican National University is seven years.

SOME FACTS FOR THE CONSIDERATION OF THE HEALTH DEPARTMENT.

To the Editor of the Medical Record.

Sir: Your article in relation to the Health Board, under date of April 30, 1892, suggests some things in reference to that department that most physicians have probably observed.

Two cases of mine recently treated will illustrate.

Mr. S——, a shoemaker, has several children. One is taken with scarlet fever. Health Board notified and promptly responded. Mr. S—— is ordered to stop making shoes. As I was present, I asked to have permission given to finish the shoes he was working on, promising to see to it that the shoes should, when finished, be sent to the Health Board for disinfection before they were sent to the shop. This was denied. However, when the department wagon called, Mr. S—— was told, "Sure any old pair will do as well," and accordingly sent an old pair of his own. The new pair was finished and sent to the shop *without* disinfection. This I learned too late to remedy the matter. Mr. S—— went to work in the shop during the child's illness, returning to the house every night.

No inquiry was made, so Mr. S—— says, regarding his other children. One was going to school, one was employed as a cash-boy in one of our large dry-goods stores, with a good chance to meet children. Two older boys were employed among men at a factory. I ordered the boy kept from school and required to see him on my call each day during school hours, as also the boy from the store, who was kept home and the firm notified. The older boys were allowed to go to work, but not to come near the patient. This last order may not have been carried out, but I thought I could trust the people, and believe they did not abuse my confidence. After the child recovered, the Health Board was notified to disinfect the rooms. They arrived promptly, but in place of disinfecting simply left something, without specific instructions, for the family to use.

Case number two was that of a widow, with two children, whose only means of subsistence was taking in washing. Health Board was notified, and, as usual, responded promptly, giving orders that no washing be taken in. Right and proper, but how was the poor woman to live? Charitable people gave me money to give to her from time to time, to aid her until the child should recover. When the child was well the Health Board was notified, so that they could disinfect. Response was prompt, but, as usual, the disinfecting was left to the family. The first trouble in all this seems to be the lack of provision by law to, in some way, reimburse people for furniture and other things destroyed by the Health Board and for provis on looking to the continuance of ordinary occupation, or in default of this a fund to aid the poor when necessary, as in the case of the poor widow. It is not in human nature to enforce quarantine as strictly where such suffering is entailed. This poor woman had no coal for her fire one day when I called.

I do not wish to criticise the Health Board authorities, for I think the suggestion relative to the substitution of shoes coming from one poor man to another was but natural, and it is not always practicable, if possible, for the same officer who ordered shoes sent down to see them after they arrive.

Had the unfinished shoes been sent down and lost, as is sometimes the case, the shop-keeper would have charged them to the workman.

I believe this risk of causing suffering to poor people tempts physicians not infrequently to omit the sending of a report.

The city recognizes the tendency to keep contagious diseases from being reported when the family lose financially thereby: in the Police Department, by allowing policemen full pay during such sickness in his family, and half pay during personal sickness—and no duty performed in either case. At least this is my information. Cannot something be done in the line suggested?

Yours respectfully,

W. Washburn, M.D.

New York, May 2, 1892.

New Instruments.

AN ELECTRIC TONSIL-SNARE.

By CHARLES H. KNIGHT, M.D.,

NEW YORK.

The "electric tonsil snare" here shown was suggested by a similar device proposed by Toison for use with the cold wire. The double cannula carrying the wire, No. 30 platinum, is attached to a solid steel shaft from which it is thoroughly insulated. The shaft ends in a ring whose vertical diameter is longer, to correspond with that of most tonsils. The ring may be of different sizes. The wire loop is shaped to adapt itself to the ring, to which it is fastened by a single fine thread at its distal extremity. The tonsil having been surrounded with the ring, traction is made upon the wire, bringing the loop in contact with the tonsil above and below. At this instant the current is turned on, the thread holding the wire is burned through, thus releasing the loop, the wire buries itself, and the further steps of the operation are simple. It is well to avoid excessive heat and violent traction on the wire, which is apt to break if drawn upon while very hot. A firmer, deeper eschar seems to follow the plan of making traction and burning alternately. It should always be remembered that the heat should be allowed to do the work, the loop being drawn down each time only sufficiently to cut through the portion of tissue that has been burned. The total result of this operation is not measured by the amount of tissue actually removed, since the parts left behind are cauterized to a considerable depth. Galvano-cautery operations in general are not to be recommended as substitutes for cutting. They are to be employed under one of the following conditions, namely, hæmophilia, vascular anomalies, anatomical peculiarities which preclude excision, refusal of the patient to be cut. This particular method is not feasible in children, except under general anæsthesia; it is only available in adults of considerable fortitude, and in protuberant tonsils from which the palatal folds are free.

The use of this "electric tonsil snare," in those very exceptional cases in which bloodless operations are indicated, is recommended for two reasons: First, with it there is no difficulty in placing the wire loop around the tonsil; and, second, the velum and dorsum of the tongue are perfectly guarded by the steel ring, which remains quite cool. It is hardly necessary to add that the ring should be adjusted over the tonsil first, to the outer side of the loop of wire, and should be pressed firmly outward with the forefinger applied to the shaft of the instrument exactly as in the case of the guillotine. The cannula may be used with any handle desired. My own preference is for the Schech or the Kuttner handle.

The instrument has been very neatly made by Meyrowitz.

20 West Thirty-first Street.

Primary Carcinoma of the Urethra is a rare condition, and one only recognized as a rule after removal and examination by the microscope. Dr. Witzenhausen reports, in the *Centralb. f. Chirurg.*, No. 55, 1891, two cases observed in the clinic at Heidelberg.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending May 7, 1892.

	Cases.	Deaths.
Typhus fever	5	4
Typhoid fever	17	7
Scarlet fever	288	46
Cerebro-spinal meningitis	2	7
Measles	733	47
Diphtheria	127	45
Small-pox	5	1
Varicella	0	0
Pertussis	0	0
Erysipelas	0	0
Leprosy	0	0
Mumps	0	0

Notes on the New Analgesics and Antipyretics.—Dr. Squibb, in his *Ephemeris*, makes these notes upon some of the popular analgesics: *Acetanilid* (antifebrin) has lost much of late of its vaunted reputation on account of its impurity. Toxic effects have been unexpectedly produced from even fairly moderate doses, although prescribers seem to differ very considerably in what they consider the proper dose. Its apparently marked antipyretic properties, with which it started out, are less relied upon than formerly. Its good effects are to be found in its analgesic and hypnotic action. Its results have been harmful in some cases of typhoid fever, especially in pregnant and nursing women. Good results are to be looked for in neurotic affections, such as lumbago, neuralgias, severe rheumatic pains, sciatica, and the like. However, it appears to be safe and useful as a hypnotic in children, especially when affected with bronchitis or croupous pneumonia. Its comparative insolubility, and thus tastelessness, together with the smallness of dose, recommend it strongly in these cases. It may be well administered by placing the drug itself, or mixed with a little sugar, well back on the tongue, rather than attempt to improvise some mixture. Notwithstanding conflicting results, this article has come to stay, and has recently been added to the British Pharmacopœia. No doubt the revisors of our own Pharmacopœia now at work will also give it attention. *Anæsthesin*, synthetically prepared, was exhibited at the last International Medical Congress in Berlin. Messrs. Gehe & Co. since then claim this to be bromacetanilid. It was a white, crystalline powder offered as a rival to cocaine in local anæsthesia. Little has been heard from it or about it since that time, and therefore we have little professional interest in it as yet. *Antikamnia*, the new "analgesic, antipyretic, and anodyne," which was so suddenly and attractively thrust upon us, proves now, upon careful analysis, to be nothing more than a mechanical mixture of acetanilid and commercial bicarbonate of sodium rubbed up into a fine powder. Its therapeutic effects have been good, but only to the same extent as acetanilid itself, with the noticeable advantage, however, of acting more quickly and in smaller doses, due no doubt to the presence of the bicarbonate of sodium. Under the above circumstances, then, it would be far better to extemporize a prescription of about seventy-five per cent. of acetanilid, and pay about one tenth the price the leading firm exacts. *Antinervin* was introduced into medicine a couple of years ago as being analytically salicylbromanilid, and similar in its effects to acetanilid, with its accompanying disadvantages. Its recommended efficiency in diabetes has not been verified, and we hear little of it professionally. It may be of interest, however, to learn that, from a careful examination, it is now concluded to consist of a mixture of fifty parts acetanilid, twenty-five parts salicylic acid, and twenty-five parts of bromide of ammonium. *Antipyrin* has lost very little of its popularity during the past year, but the profession has been gradually learning to use it with caution. Several very trying poisoning cases, with some deaths, have occurred from its use, even after moderate doses; but the larger proportion undoubtedly were not entirely due to the antipyrin. *Phenacetin* has justly grown in favor during the past year. It had a slight set-back at one time, due to a poisoning case, but it was finally found that it had been mixed with acetanilid for commercial gain, as the prices of the two vary considerably. It has now become official in the British Pharmacopœia.

Galen's Use of Medicines. Theriaca.—Regarding the use of special medicines by Galen, I must refer to Dr Gasquet's article, indicated in the first foot-note, where many interesting details and references on this subject may be found; but I cannot pass over the great remedy called "Theriaca." For compounding this Galen had a great reputation. This word theriaca (from which our word treacle comes, from a superficial resemblance between them) is derived from the Greek *θηριακα φάρμακα* antidotes against the bites of wild beasts—from *θηρίον* and *θήρ*, a wild beast. Originally devised as an antidote to such bites, it came to be used, in certain of its forms, as an antidote to other poisonings, to which important people were specially liable; and from this the term came to be applied to remedies regarded as antidotal to disease. Opium was probably the most important ingredient in many, if not all, the forms of theriaca, and powdered snakes may be regarded as the most striking, from the point of view of curing *per similia!* The number of ingredients varied, but was always enormous; even in this modern French Codex (1866), the ingredients of "thériaque" number 57, including, strange as it may seem, not only "opium de Smyrne," but also "vipères sèches!" Galen informs us that not a few, and among them the Emperor Marcus Aurelius himself, took a daily dose of theriaca as a precaution or antidote.—*British Medical Journal.*

A Medical Libel Suit Amicably Settled.—A libel suit against Mr. Lawson Tait, of Birmingham, brought at the last Manchester assizes, has been placated in some way out of court, very much to the satisfaction of English medical circles. Mr. Tait, as a surgeon, has many an admirer in this country, but when he is contemplated in the light of a controversialist he has not very many imitators here. He reminds us of Dr. Johnson's definition of a Scotchman as being "a person who is always positive, and sometimes right." In this libel suit, if the account given in the London papers is reliable, Mr. Tait was positive and wrong. Briefly narrated, the trouble arose in this manner: Dr. Andrew Denholm had treated a Manchester lady-patient according to the Apostoli method of electrolysis, her disease being regarded as due to a fibroid uterine tumor. An accident in the use of the electrodes caused a vesico-vaginal fistula. On this account, Dr. Denholm lost his control of the patient, and she passed into the treatment of Mr. Tait, who did a laparotomy and removed the growth. But the patient died, and Mr. Tait wrote a letter to the husband of the lady, saying that in his opinion the death was attributable to hemorrhage, due to rupture of a vessel caused by the injurious inflammation and sloughing set up in the tissues by the electrical treatment. But for this, Mr. Tait stated in his letter, the case would have been unhampered, and recovery after operation nearly sure. When the knowledge of this letter came to Dr. Denholm, he could not rest under its aspersions, but caused an autopsy to be made on the deceased patient, in the presence of a competent jury or company of medical men. The autopsy was reported as refuting entirely the allegations of Mr. Tait as to the effects of the earlier treatment by electrolysis; there had been no inflammation or adhesions, or hemorrhage of any moment, sufficient to determine the death of the patient. The fatal issue was apparently caused by peritonitis.—*Journal of American Medical Association.*

Original Lectures.

NEW OUTLOOKS IN THE PROPHYLAXIS AND TREATMENT OF TUBERCULOSIS.

THE MIDDLETON-GOLDSMITH LECTURE FOR 1892.

BY FRANCIS P. KINNICUTT, M.D.,

PHYSICIAN TO ST. LUKE'S HOSPITAL AND THE PRESBYTERIAN HOSPITAL, NEW YORK.

GENTLEMEN: When your Committee did me the honor to request my acceptance of the Middleton-Goldsmith lectureship of the present year and suggested the subject, "The Present Aspect of the Treatment of Tuberculous Disease, and Especially of Pulmonary Tuberculosis," my first inclination was to decline. Their representations, that a review of this subject was particularly desirable at the present time and would serve a practical purpose, have alone induced me to undertake a difficult task.

The lecture has been postponed beyond the customary time of its delivery, in the hope that investigations which have been carried on during the past winter in St. Luke's Hospital, and in the Pathological Laboratory of the College of Physicians and Surgeons, might be sufficiently advanced to be incorporated in it. This hope, in part, has been fulfilled.

Any consideration of methods of treatment of infectious diseases at the present time must necessarily be in the light of modern pathology and bacteriology. Through the discoveries in this field of medicine, the term treatment has acquired a new significance. A large number of the infectious diseases of human beings and of animals have already been shown to have their origin in specific pathogenic living organisms; and there are strong reasons for believing that a similar etiology will be demonstrated in the near future for all diseases hitherto included in this category.

In the infancy of bacteriology it was not unnaturally assumed that the sowing of the seed was alone necessary for the production of a disease; that if once the specific germ gained access to the economy its particular effects would certainly follow. The "possession of a self-protecting power by the organism of man and of the higher animals, which could exercise its influence within certain limits, either in arresting the development of the living exciters of disease or in counteracting their poisonous products," was hardly dreamed of. To-day the splendid discoveries of bacteriological research have abundantly demonstrated that an unceasing contest is being waged between the growing power and toxic activity of the pathogenic microphyte and the living organism.

In this connection what can be of more absorbing interest than the discovery by the distinguished plant physiologist, Professor Pfeffer,[1] of the group of phenomena to which he gave the name of chemotaxis, the definite relation between vital movement and chemical action. Later it was suggested by Dr. Leber that the emigration of leucocytes in the human body was due to the same power. In other words, that certain harmful substances in the living tissues, embracing effete materials, living pathogenic organisms, and viruses of various kinds, are, agreeable to a rudimentary sense of taste, as it were, in the leucocytes, which are thus allured from the media in which they commonly live toward the attracting substance.

The mustering of the leucocytes in troops, in the neighborhood of the bacterial invaders of the body, as a direct or indirect protection to it, is almost as dramatic as it is important. This action of the leucocytes, in virtue of their chemotaxis, and the final incorporation or digestion by them of the bacteria, constitutes Metschnikoff's well-known theory of phagocytosis and phagocytic immunity.

Further, we may refer to the investigations of Büchner[2] and Roemer, showing the association of a general leucocytosis with febrile inflammatory processes. They found that within eight hours after the intra-venous injection in rabbits of various proteids, there was marked leucocytosis; the relation of white to red blood cells on the evening of the fourth day of the daily injection of solutions of the protein of the bacillus pyocyaneus (green pus) was 1 to 38, the absolute number of the red blood-cells remaining unchanged. It should be mentioned that the office of policeman, on the part of the leucocytes, is not considered proven at the present time by many. Their work as scavengers is acknowledged, but it is believed that the true guardianship of the body resides in the body fluids; in other words, that the destruction of bacteria is accomplished by the germicidal power of the latter, and their removal only is effected by the leucocytes.

Finally, we may refer to the investigations, which have shown that, "while the living tissues and fluids of the body possess the power, in varying degree, of arresting the development of living, disease-producing organisms, and of eventually destroying them, certain life products of the latter are capable of impairing or inhibiting this protective power."

In view of such facts preventive medicine must necessarily embrace the means of promoting the victory of the organism in its contest, either by strengthening its defences or by weakening or destroying the power of the growing microphyte.

With our present knowledge of the various media in which the specific living exciters of disease most commonly lurk, it should be a matter of reproach if we fail in securing a more efficient prophylaxis than has been possible in the past.

Previous to 1882 the pulmonary lesions of tuberculosis had been accurately described, and Villemin, as a result of his successful inoculations of animals, had declared it to be a specific infectious disease. With the announcement of Koch, on March 14th of the above year, that he had discovered not only the constant accompaniment but the cause of the tuberculous process, the infectious nature of tuberculosis was finally established, and the nature of the relation between specificity of cause and specificity of process in this disease was determined.

Before proceeding further it will be advantageous to have accurately pictured in our minds the pulmonary lesions which are directly or indirectly due to the tubercle bacillus. The list is indeed a formidable one. Miliary tubercles both single and conglomerate, larger and smaller areas of epitheloid cell-growth called diffuse tuberculous tissue, and various aggregations of these (often in a state of more or less advanced coagulation necrosis), disintegration, and excavation as a result of the latter, cicatricial formation, peri-bronchitis, and extensive inflammatory consolidations specific in nature; and finally we must bear in mind the bronchitis and lobular pneumonias, probably simple (unspecific) in character, so frequently present in tuberculous lungs.

In the light shed by modern research upon the posses-

sion by the organism of man of a self-protecting power against pathogenic organisms, with a knowledge of the specific organism which causes tuberculosis and the lesions which are directly or indirectly produced by its presence in the economy, we are proportionately equipped to attempt to consider the measures, prophylactic and remedial, which have been proposed to cope with the disease.

Prophylactic measures must necessarily consist of those designed to destroy the vitality of the bacillus outside of the human body, to minimize the sources of infection, and to render the tissues insusceptible to its presence.

Three possibilities suggest themselves as specific means for exercising a remedial effect. They are: 1. The discovery of a method of treatment capable of destroying the bacillus within the body. 2. Of some substance, organic or inorganic, which by its introduction into the body may so modify the action of the bacillus as to deprive it of its harmful effects. The possible abstraction of a constituent of its protoplasm or of its metabolic products, analogous to the tetanus or pneumonic anti-toxin, suggests itself in this connection 3. The discovery of a principle capable on introduction into the economy of increasing the germicidal power of the fluids of the body by stimulating cell activity, upon which it ultimately depends, or by such stimulation inducing connective-tissue changes in tuberculous tissue, or both.

Prophylaxis.— I shall first consider the prophylaxis of tuberculosis, so far as it relates to destroying the vitality of the bacillus outside of the human body and to minimizing the sources of infection.

With the discovery of the specifically infectious nature of a disease the means of infection are not necessarily directly evident. In tuberculosis a series of brilliant investigations quickly threw much light upon this point. Following Koch's discovery, it was very early shown that the bacilli were not contained in the air expired by patients suffering from pulmonary tuberculosis; on the other hand, that their sputum contained bacilli in enormous numbers. It was further shown that the bacilli were incapable of escaping from fluid media, and finally, that the sputum in the dry state, conveyed in the form of pulverized atoms by currents of air, was the most common source of infection. Successive investigations demonstrated that the stools of human beings afflicted with the intestinal form of the disease, the discharges from tuberculous ulcers, glands, and bones, were positive, if infrequent, vehicles of infection; and finally, that the milk of tuberculous cows, with or without disease localized in the udder, and tuberculous meat, were capable of producing tuberculosis in the consumer.

It will be interesting to refer at somewhat greater length to inoculation experiments and clinical observations bearing on the above points.

The elaborate investigations of Cornet [3] in the Berlin Institute of Hygiene, in regard to the distribution of the tubercle bacilli in the air, are particularly instructive. The dust from 21 wards of 7 hospitals, from 3 asylums, 2 prisons, from the living-rooms of 62 phthisical patients in private practice, from "out-patient" departments, from the public streets, and from inhalation experiment rooms was gathered, and its virulence or innocuousness determined by inoculation of susceptible animals. Of 94 animals inoculated with the dust of hospital wards, 20 became tuberculous. Virulent bacilli were obtained from 15 out of 21 medical wards. Negative results, on the other hand, were obtained from the dust of the surgical wards, also from that of the streets and the inhalation-rooms investigated. Of 170 animals inoculated with dust from the living-rooms of consumptives, 34 became infected. As 91 of the 170 died of septic disease, it is probable that the above percentage of animals in which tuberculosis was produced does not accurately represent the specific (tuberculous) virulence of such dust. The dust was taken from the walls, articles of furniture, picture-frames, etc. From the room of a consumptive in a private house, virulent bacilli were obtained six weeks after her death.

Cornet records the fact that he did not once find infective bacilli in the rooms of those patients who used only spittoons for the sputum, although especially careful search was made in these instances. Equally valuable evidence on this point is furnished by Trudeau.[4] In his sanitarium at Saranac Lake, where rigid rules in regard to the use of proper receptacles for the sputum are enforced and its efficient disinfection or destruction is accomplished, not a single employee has acquired tuberculosis during the six years since its institution.

In Dettweiler's sanitarium at Falkenstein, where presumably similar precautions are taken, a similar experience is claimed.

With such observations before us, further clinical statistics may be unnecessary, but are not without interest.

In response to questions sent in 1883, by the Collective Investigation Committee of the British Medical Association, to physicians throughout Great Britain,[5] asking for their personal experience on the communicability of phthisis, 1,078 communications were received. Of these, 673 were to the effect that cases of tuberculosis originating in infection had not come under their notice. Of the remaining 405, 261 were regarded by the Committee as positive in evidence of communicability, 39 as doubtful, and 105 as negative. Among the affirmative observers 192 reported cases of probable infection of husband by wife and the converse, and in 130 of these cases there was an entire absence of inherited predisposition on the part of the person infected.

Turning to our own country, the investigations of Flick [6] are of much interest. The localization of, and mortality from, tuberculosis in one of the wards of the city of Philadelphia, for a period of twenty-five years preceding 1888, were very carefully studied by him. It is shown that while less than one-third of the houses of the ward became infected with tuberculosis during the twenty-five years prior to 1888, considerably more than one half of the deaths from this disease during the year 1888 occurred in infected houses. Inasmuch as there were more than twice as many non-infected as infected houses in the ward, a preponderance of deaths in non-infected houses would be expected.

Cornet's investigations of the health statistics of the Catholic Nursing Orders of Prussia [7] may be considered as supplementary to those of the same author which have already been described. Thirty eight convents were selected, representing a yearly average of 4,028 persons, and the statistics relate to the twenty-five years preceding the year 1889. It is known that the general annual death-rate from tuberculous disease is from one-seventh to one-fifth of all deaths. Among the above orders the enormous average mortality of 62.88 per cent. is shown to be due to tuberculosis alone. In nearly one-half the convents it even rises to seventy-five per cent., and in two "Mother Houses" it was the sole cause of death. In others, the death-rate from this disease varies from forty to fifty per cent.

Cornet says that the different mortalities may be explained by the fact that some of the nurses are engaged in attending altogether, or for the most part, upon surgical cases. The average age at death of the inmates is 36.27 years, lower by ten years than that of men engaged in trades notoriously the most unhealthful, *i.e.*, file-cutters, coppersmiths, locksmiths, blacksmiths, cotton-spinners, etc. If the mortality due to tuberculosis, and that resulting from other diseases commonly regarded as infectious, are both deducted from the death-rate in the Prussian state and in the convents, it is shown that, up to the age of forty years, the death rates in state and convents are remarkably equal From forty to sixty years, the mortality due to non-infectious diseases is less in convent than in state. Even admitting the insanitary conditions of convent life, it is impossible to believe, with our present knowledge of the etiology of tuberculous disease, that

it can produce it. On the other hand, these conditions are of the kind to lead to its rapid extension, when once introduced. It should be mentioned that the health of all persons on entering the nursing communities is excellent, admission being dependent upon medical certificates to this effect.

Among the numerous investigations,[8] [9], [10], of the infectiousness of the milk of tuberculous cows, I shall only refer to the very brilliant ones of our countryman, Dr. Ernst, of the Harvard Medical School.[11] They surpass in their extent and importance those of the continental observers. Experimental inoculation in rabbits and guinea-pigs, and feeding experiments in calves and pigs with both the milk and cream of tuberculous cows without disease of the udder, proved in the most positive manner that such milk is capable of producing tuberculosis in the consumer. Incidentally, in experiments with milk taken at random from the common dairy supply of Boston, virulent bacilli were found in two instances.

If Dr. Ernst's experiments are supplemented with the clinical fact of the frequency of intestinal and mesenteric tuberculous disease in children, and with the statement, made in the form of a resolution, by the United States Veterinary Association in 1889, that from ten to fifteen per cent. of the dairy stock of the Eastern States is tuberculous, this subject assumes very grave importance. Although investigations have shown that tuberculous meat as such is infective, further experiments are necessary to determine whether those parts of a tuberculous animal usually used for food, and not specifically affected, are harmful.

I have been able to collect a large number of cases of probable inoculation tuberculosis in the human being. Many of them occurred through infection of post-mortem and dissection wounds. Among others the following are of interest :

A healthy girl, aged fourteen, without inherited predisposition, became locally infected through wearing the ear-rings of a consumptive. A tuberculous infiltration of the glands and general infection followed.[12]

A male child, very vigorous at birth, began to suffer, when three years of age, from eczema of the skin of the abdomen. Bacilli were searched for, but not discovered. After four years of age he constantly slept with his consumptive mother, and bacilli were shown to be present in the eczematous vesicles.[13]

A student received a slight wound in dissection ; a nodule appeared at its site, and a swelling of the glands of the forearm followed. The glands were excised and showed central cheesy degeneration.[14]

Ten Jewish boys were circumcised by the same physician only a short time before his death from consumption. There is positive evidence that the saliva of the operator came in contact with the preputial wounds. The first symptoms of infection developed ten days later. Three of the children died of tuberculous meningitis, three of marasmus, and one of intercurrent diarrhœa. Three survived, but developed tuberculous adenitis.[15]

Accumulated experimental and clinical investigations in demonstrating the most common sources of infection, viz., the sputum of patients suffering from pulmonary tuberculosis, the milk of tuberculous cows, and finally, though to a much less extent probably, tuberculous meat, clearly indicate the direction which prophylactic measures should take.

The enormous number of tubercle bacilli contained in the sputum of patients suffering from pulmonary tuberculosis, even admitting that many of them are dead, as Kitasato very recently has shown, is well known. In a series of investigations kindly made for me by Dr. T. Mitchell Prudden, in 1891, as many as 21,460,000 were computed to be present in the daily sputum of a single patient. Nuttall's experiments,[16] conducted in the Johns Hopkins laboratory, give quite similar results.

Sawizky [17] has shown, moreover, that tuberculous sputum, dried and preserved under the conditions which usually obtain in the dwelling-house, preserves its infective properties for two and a half months.

Stone's experiments,[18] if corroborated by further investigations, apparently show that its virulence may be extended for as long a period as three years. If we further consider the exceptional resistance of the tubercle bacillus to the action of both chemical and other antiseptics, the efficient disinfection or destruction of tuberculous sputum becomes a matter of vital importance.

Chemical Disinfection.—Carbolic acid, potassa, sulphate of copper, and chloride of zinc, all in solutions of 1 to 500, were found by Grancher and de Gennes to be useless.[19] Histological examination of the sputum so treated showed no change in the appearance of the bacilli, and inoculations proved that they were still active. Later experiments [20] have demonstrated that carbolic acid, even in ten per cent. solution and after twenty-four hours' admixture with the sputum, is without effect. Corrosive sublimate is valueless, through the coagulation produced by it of the albuminoids contained in the sputum. The experimental investigations of Schottelius and Spengler,[20] with the newer antiseptics—creolin, aseptol, and lisol —of which much was hoped, have also been disappointing. Ten per cent. solutions of creolin and aseptol were found to be absolutely without effect, even after twenty four hours Lisol, however, in ten per cent. solution, proved to be capable of rendering the sputum sterile in twelve hours.

These results indicate in the most positive manner that we possess no practical means at present for efficiently disinfecting sputum by chemical antiseptics.

Experiments with heat, on the other hand, have shown that the tubercle bacilli rarely survive a temperature of 80° C., and are invariably killed at temperatures varying, according to different observers, from 90° to 100° C.[21] Simple rinsing of the cups or other receptacles of the sputum with boiling water is not sufficient, and is not without danger to the attendant. Numerous observers report cases of infection of cuts from sputum (v. Eiselsberg,[22] Fleur,[23] Holst,[24] L. Pfeiffer,[25] and others).

In view of these facts, every consumptive should possess the knowledge that while his disease is in reality a menace to those about him, the foil is within his reach. He should be taught never to use a handkerchief for the sputum, never to spit upon the floor. An appropriate receptacle of glass, china, or paper, partially filled with water should be provided for the sputum, which should be thoroughly disinfected or destroyed at least once in twenty-four hours. For its disinfection in hospitals an ordinary Arnold's sterilizer, of sufficient size to accommodate all the cups of a ward, and in which they should be placed daily for a half hour, may be used.

A far better method, in my judgment, is the destruction of the sputum by fire. The method at present in successful use in St. Luke's Hospital, and which is of easy application in private houses, consists in the use of paper-boxes, which are daily supplied to each patient, and at the end of twenty-four hours destroyed, with their contents, by fire. They are of convenient size, are very inexpensive, and the preparation used in their construction prevents all leakage. The floors and the walls of living rooms and of hospital wards of consumptives should be scrubbed or wiped with damp cloths, not swept or dusted. The cast-off clothing of such patients should be submitted to the action of live steam or to the degree of heat described as sufficient to destroy the tubercle bacillus.

Public sentiment, in the absence of legislation, should compel the proprietors of hotels and boarding-houses, at health-resorts, at least, to take such measures as can be designated, with our present knowledge, for disinfecting the living-rooms of consumptives. Further investigations are urgently needed to determine the most efficient and practical means for accomplishing this object.

A further most important prophylactic measure consists in the systematic veterinary inspection of dairies, particu-

larly those of large cities, and of slaughter-houses. Commercial considerations have secured the necessary legislation for the inspection of the pork products of the United States; a consideration of the public health should be sufficient to secure a similar legislation to minimize the sources of infection of tuberculous disease.

A bill for the inspection of dairies and the slaughter of tuberculous animals, I am happy to state, will probably be introduced in the legislative houses of the State of New York during the present session. Such an example, it is reasonable to hope, would gradually be followed by the Legislatures of other States.

In the meantime, in the absence of necessary legislation, the only safeguard possessed by the public against possible infection through dairy products consists in the sterilization of milk and cream by boiling, or through the use of steam sterilizers.*

Many of the prophylactic measures which have been mentioned have already been embodied in the form of suggestions or in laws by various governments and municipalities abroad, and the Board of Health of the City of New York has issued some admirable rules "to be observed for the prevention of the spread of consumption."

In considering the prophylaxis of tuberculosis I have purposely confined myself to measures designed to destroy the vitality of the bacillus outside of the human body, and to means for minimizing the sources of infection, in the belief that such efforts are of far greater relative value than those directed toward increasing the resisting power of the individual. I shall even go further, and thus cease to be open to the reproach that the clinician's interest in the therapeusis of the disease is almost to the exclusion of that in its prophylaxis, and assert that infinitely more can be accomplished toward the elimination of this terrible scourge by making practical use of our present exact knowledge of its etiology and prophylaxis than by any or all therapeutic measures at present at our command. As has been well said, "It is the seed of the disease, without the implantation of which there can be no harvest of death, that we are now most able to reach and destroy." We shall fail, then, in our duties as true physicians, if we do not scatter broadcast among the laity this knowledge. From a full appreciation of the dangers at their doors, and a knowledge of the means capable of diverting them, surely good fruit will be borne, even to the *enactment* and *enforcement* of laws for the protection of the public health.

In turning our attention to the remedial treatment of tuberculosis, our thoughts naturally are directed first to Koch's tuberculin.[26] His hypothesis of its specific mode of action is as follows: He particularly states that other explanations are possible and may be more correct. The tubercle bacilli in their growth produce in the living tissues, just as in artificial cultivations, certain substances which have various, but always deleterious, effects upon the living elements of their surroundings, the cells. Among these substances is one which, in a certain concentration, destroys living protoplasm and causes it to undergo what is known as a coagulation necrosis. The necrotic tissue is unfavorable to the nutrition of the bacillus; its further development is checked, and finally, in some cases, its death follows. If the amount of the necrosis producing substance be artificially augmented, as he believes it to be by the introduction of tuberculin into the system, not only will the extent of the necrosis be increased, and consequently the conditions of the nutrition of the bacilli be more unfavorably affected, but also more completely necrosed tissues will disintegrate and slough, and where this is possible, take with them the inclosed bacilli, carrying them outward. Large doses of tuberculin are capable of giving rise to a certain amount of pyrexia and other symptoms in healthy persons, he believes, through irritative influences exerted upon certain elements of the tissues, probably on the white corpuscles of the blood, or cells closely related to them.

The necrosis-producing substance in tuberculin Koch now tentatively believes to be an albumose, or a substance closely related to it. Many elaborate criticisms of this hypothesis, both theoretical and based upon experimental and clinical investigations, have appeared during the past year. In a very recent monograph by Rosenbach,[27] the author denies both a specific affinity of tuberculin for tuberculous tissue and the specific action claimed for it. The general reaction and constitutional disturbance following its inoculation he believes to be due to a general irritation set up in the body, which, according to its degree, can assume the characteristics of an inflammatory action, in some cases even of a purulent type. The degree of the reaction, particularly of the fever, depends upon the predisposition of the individual to febrile disturbance. Similar constitutional disturbances have been shown to follow the inoculation of cantharidal salts and the protein of other bacteria. Rosenbach asserts that the specific activity of tuberculin can only be demonstrated when it is proved that substances derived from other micro-organisms can produce fever exclusively in subjects who are the hosts of bacteria of the same kind, and further, that they can evoke reactions only in the tissues in which changes have occurred from their action, and elsewhere remain without effect. He claims that hitherto this has not been shown. The author expresses a guarded opinion whether tuberculin produces an actual necrosis of tuberculous tissue; if it occurs, he believes it is not a coagulation (specific) necrosis, but rather is secondary to an acute inflammatory process and exudation.

A new light has been thrown on the nature and action of tuberculin through the investigations of William Hunter, of England, and the German pathologist Klebs. As early as January, 1891, the former began his investigations.[28] Starting with the assertion of Koch that the remarkable properties possessed by it, unfortunately for evil as well as for good, were due to a single active principle which constituted but a fractional part of the extract, he believed that the chemical behavior of this hypothetical principle, which was described by the discoverer as a derivative of albuminoid bodies, could not possibly apply to any one known chemical substance.

His studies had for their object: 1. To isolate the chief constituents of tuberculin and to determine their chemical nature. 2. To ascertain their action with special reference to their power of inducing the two most characteristic effects of tuberculin, viz., local inflammation and fever. 3. To ascertain how far it was possible to eliminate all substances having an injurious action, and thus to obtain remedial without injurious effects.

His results may be summarized as follows, under the heads of composition, action, and therapeutic value. The chief substances found in tuberculin are: 1, Albumoses;* 2, alkaloidal substances; 3. extractives, small in quantity and of unrecognized nature; 4, mucin; 5, inorganic salts; 6, glycerine and coloring matter.

Having ascertained that the only substances present in tuberculin with which its active properties could be associated were albumoses—organic bases of alkaloidal nature—and probably various extractives, he proceeded to determine, by experiments on mice and guinea pigs, to which of the above substances tuberculin owed its characteristic properties, remedial and otherwise.

Four modifications of the original tuberculin were accordingly prepared by him. He has given to them the designations A, C, B, and CB, and these terms will be retained in the present paper.

From extensive investigations with these modifications he feels warranted in concluding—

1. That tuberculin owes its activity not to one prin-

* Investigations conducted in the Imperial Health Bureau of Berlin demonstrate that tubercle bacilli also retain their vitality in butter and cheese frequently for weeks.

* Albumoses; chiefly proto-albumose and deutero-albumose, along with hetero-albumose, and occasionally a trace of dys-albumose.

ciple, but to several; that its action in producing local inflammation, fever, and general constitutional disturbance is not a simple but an extremely complex one.

2. That its remedial and inflammatory actions are connected with the presence of certain of its albumoses, while its fever-producing properties are chiefly associated with substances of a non-albuminous nature.

3. By the adoption of certain chemical methods it is possible to remove the substances which cause the fever, while retaining those which are beneficial in their action.

4. That the fever produced by tuberculin is thus absolutely unessential to its remedial action. (He is inclined to believe that the inflammation is almost similarly unessential, although admitting that under certain circumstances it may assist the action of the remedial substance.)

5. That tuberculin possesses a truly remedial action, and that this is to be found in a protein, *i.e.*, in an albuminous substance derived from the plasma of the bacilli themselves, and not formed by their action upon the surrounding tissues, and finally, that it is possible to isolate largely this protein.

Dr. Hunter's clinical investigations, in which he has been assisted by Mr. Watson Cheyne, with the above modifications of tuberculin have led him to assert tentatively the following propositions: Modification A differs but slightly in its action from tuberculin. Modification C differs from tuberculin in being almost completely freed from the substance which gives rise to local inflammation. It contains, however, in a special degree, the fever-producing agents, which may be regarded as interfering with the remedial properties, and favoring rather than retarding the growth of the bacilli.

Modification CB contains the remedial substance present in C, freed from the fever-producing agents. Its use, moreover, is unattended with any of the other constitutional symptoms following the employment of tuberculin.

Modification B contains the remedial properties of CB, with the additional property of inducing local inflammation. Its action is free, so far as has yet been observed, from ill effects.

From the marked improvement which Dr. Hunter has seen occur in cases of ulcerative and other forms of lupus, where it is possible to watch the local changes from day to day, under treatment both with B and CB, he believes the activity and probable remedial power of these modifications to be demonstrated.

It yet remains to be determined whether the improvement noted in his cases will be more or less permanent. The absence of marked local inflammation or of necrotic changes accompanying their use leaves the mode of action of the above modifications of tuberculin a matter of more or less speculation at the present time. I shall refer later to the clinical investigations of other observers, and to some personal ones, with Dr. Hunter's preparations.

Professor Klebs's researches have apparently been based on the same line of thought as the above, but were made quite independently of them.[49] Convinced that tuberculin produced in the human being many effects which had nothing to do with its action upon tuberculous tissue, and which could be avoided without affecting the latter property, he submitted tuberculin to various chemical processes with the view of freeing it from its alkaloidal substances. Its noxious properties reside in the latter he believes. He claims that the extracted principle represents the secretions of the tubercle bacilli, and is a pure albumose. Experimental investigations in animals indicate that the injection of large doses of tuberculocidin, as he terms the albumose, previous to inoculation with pure cultures of the bacillus, delays the development of tuberculosis to at least twice the usual period; moreover, that a complete resolution of previously developed tubercle may occur under its use.

The best results in animals were obtained when the tuberculocidin was injected simultaneously with inoculations of the bacilli. In such animals, killed three months later, tubercle was scantily present, and few bacilli were found. In cases where treatment was begun six weeks after experimental inoculation, and continued for twenty-five days, either complete healing or a high degree of retrogradation of the tuberculous lesions was observed.

Of seventy-five critically observed cases of pulmonary tuberculosis in the human being, treated with tuberculocidin, 18.6 per cent. are claimed to have been cured, and sixty per cent. improved. In a single case of supposed tuberculous meningitis the symptoms also improved. Cases are reported in detail by Klebs in which a successful issue occurred, both tuberculin and creasote having previously failed to give good results. The treatment being practically unattended with constitutional disturbance or fever, there is no interference with the customary life and occupation of the patient.

As far as I am able to judge from Klebs's statements, the remedial properties of tuberculocidin reside wholly in its germicidal power, *i.e.*, in its ability to destroy the tubercle bacillus within the human body. He expressly states that no inflammatory process or necrosis of tissue is produced by it.

If Klebs's very positive statements on the above points are borne out by further extended observations, a far-reaching and very brilliant discovery has been given to the world.

In concluding his report Klebs remarks: "That it only remains to determine the limitations which control the cure of the disease produced by the specific bacillus, whose destruction we have succeeded in accomplishing. The first cause may vanish, and yet the pernicious results of the conditions developed from it remain. When advanced destruction of pulmonary tissue has occurred, where the general vitality has greatly depreciated, and emaciation and marked impairment of the heart's function have taken place, cure is no longer to be expected, even with the removal of the first cause of these conditions."

We have now to consider some very interesting and noteworthy investigations of Roemer and Büchner.[50] The former, as the result of his experimental researches, has made the surprising announcement that the same reactions can be obtained in tuberculous guinea pigs from inoculations with proteine containing extracts from the bacillus pyocyaneus (green pus) as with tuberculin. He found that tuberculous animals died quickly after injections of such extracts, while healthy animals lived; that lesions occurred in the liver and spleen of such animals, apparently quite similar, both macroscopical and microscopical, to those described by Koch as due to the specific action of tuberculin. Büchner has corroborated Roemer's observations of the effect of injections of the proteine of the bacillus pyocyaneus, and has found similar effects to follow the use of the proteine of other bacilli, viz., pneumo-bacillus (Friedländer) and the bacillus prodigiosus. Inoculations of healthy men with minute doses of the proteine of the pneumo-bacillus or the prodigiosus were followed by redness and swelling at the point of injection and a local rise of temperature, which gradually disappeared, and of quite similar character in the different persons experimented upon. Constitutional symptoms were not produced, Büchner suggests, on account of the smallness of the dose administered. The pronounced local reaction, in comparison with that of tuberculin, he believes to indicate a more serious action of the proteine. Büchner concludes his report of his investigations as follows: "Are the proteine extractives of the tubercle bacillus alone capable of exciting a latent irritation to an appreciable inflammation and necrosis? Are not other ordinary exciters of inflammation, especially proteines from harmless kinds of bacteria, possessed of the same power?" The observations reported by him, he thinks, speak favorably for such a possibility, and open, therefore, in a practical manner, new and perhaps not unimportant outlooks.

In the light of extended experimental investigations

and of numerous clinical observations the incorrectness of many of Koch's original hypotheses and conclusions is evident. It has been shown that tuberculin contains not one, but several active principles, respectively capable of producing different effects; that whatever remedial action it may possess resides apparently in certain of its albumoses, while its harmful properties are seemingly due to the non-albuminoid substances present in the extract. With the knowledge that tuberculin is the concentrated fluid medium in which the bacilli have been growing, thus presumably containing both the products of their growth and the proteins derived from their bodies, Prudden's experimental studies[31] of the action of dead tubercle bacilli would seem to be further corroborative of the above views. His experiments indicate that the dead bacilli, freed so far as is possible from the products of their growth, are capable of enormously stimulating cell activity and of producing lesions morphologically similar to tubercle, but "which are not indefinitely progressive, and do not tend to the production of an advancing coagulation necrosis, and finally, do not induce an infectious disease."

A legitimate conclusion from these observations would seem to be that the coagulation necrosis, which Koch's hypothesis regards as the remedial mode of action of tuberculin, is dependent upon a metabolic product of the growth of the bacillus.

In view of the remedial effects obtained by Hunter, Cheyne, and Klebs from the use of a tuberculin presumably freed from metabolic products, and the apparent demonstration by Prudden that a constituent of the protoplasm of the dead bacillus, probably a proteine, is capable of enormously stimulating cell activity, it is justifiable to feel that much light has been thrown on a most complex question.

Whatever beneficial results were obtained from Koch's original tuberculin, I am convinced were not through, but in spite of, a production of coagulation necrosis; and that the benefit claimed to-day by many, from its use in exceedingly small doses, is partly through the avoidance of such an effect. In exceedingly minute doses it is possible that the action of the cell-stimulating proteine preponderates, and thereby a remedial influence is exerted.

A rather large clinical experience, now extending over a period of eighteen months, leads me to reiterate an opinion previously expressed, "that tuberculin contains a remedial principle."

This view is shared, among our own countrymen, by Trudeau and von Ruck, gentlemen who have enjoyed in their sanitaria the widest possible opportunities for thoroughly studying the subject.

In a recent communication by Schede, of Hamburg,[32] than whom no continental surgeon has a larger clinical experience, a similar opinion is expressed. In concluding this portion of my subject I cannot but express my abiding and earnest belief that the continued and exhaustive investigation of Koch's discovery will lead either to such modifications of the original extract, or to the preparation of a new one based upon a similar principle, as will place in our hands an agent specific in character and remedial in tuberculosis in a degree hitherto believed to be unattainable.

The results obtained in the wards of St. Luke's Hospital in the treatment of pulmonary tuberculosis with modifications of tuberculin, already effected, will be appended to the present lecture.

Treatment of Pulmonary and Laryngeal Tuberculosis by the Cantharidates.—In February, 1891, Professor Liebreich, in a paper read before the Berlin Medical Society, announced that he had discovered a new remedy for the treatment of tuberculous disease. The property of cantharidin, when taken internally, of producing an exudation of serum from the capillaries not only of the kidneys, but also of the lungs and other organs, unattended with increased arterial tension, hyperæmia, or extravasation of blood, when used in sufficiently small doses, forms the basis of his theory.

The irritability of the capillaries, according to Liebreich, varies in different parts of the organism in health; in an abnormal state, such as may be assumed to be their condition at the site of local disease, this irritability is increased. By furthering such irritability by the use of the cantharidates, an exudation of serum occurs which may favorably affect tuberculous tissue in two ways: 1, by stimulating cell activity and nutrition; 2, through the germicidal action of the serum upon the bacteria.

His experimental investigations apparently indicate in a measure the correctness of his theory. The remedial effects which have followed the use of the cantharidal preparations, while occasionally striking, especially in the case of laryngeal tuberculosis, fall short of securing to them, it seems to me, a permanent place among the therapeutics of tuberculosis.

Their apparent action is in harmony with one of the possible means of a remedial treatment of tuberculosis. Cell activity is stimulated and specifically diseased tissues are subjected to the germicidal action of the blood-serum artificially increased at the site of the disease. There is a failure possibly in the degree rather than in the kind of action. The preparations at present employed are the potassium and sodium cantharidates. They are administered hypodermatically at intervals of forty-eight hours or longer, and in doses of $\frac{1}{60}$ to $\frac{1}{30}$ grain. The latter strength not infrequently causes symptoms of vesical and renal distress. Their use is contraindicated in the presence of intestinal and renal disease, and in patients with marked hectic.

Treatment with the Serum of Dog's Blood.—The interesting experimental investigations of Richet and Héricourt, announced during the past year to the French Academy of Sciences,[33] with the serum of dog's blood in the treatment of tuberculosis, are in the line of thought that at present underlies our attempts to cope with the disease. These observers have been able to demonstrate that in rabbits inoculated with a culture of the tubercle bacillus, the evolution of tuberculosis can be arrested by subsequently subjecting the animal to injections of dog's serum. When very virulent cultures are employed, the evolution is only delayed. Injections of a healthy animal with the serum prevent the development of experimental tuberculosis at a later period. The effective substance has not been identified as yet, but a small dose of the serum is sufficient (one-half cubic centimetre per kilo of the rabbit).

The clinical results obtained in tuberculous disease of human beings by this method of treatment, which has been fully tried in the Paris hospitals, would indicate that it also fails rather in the degree than in the kind of its action. It certainly acts as a potent stimulant to cell activity. Whether it possesses another action is undetermined.

Chloride of Zinc Treatment.—I shall briefly refer to the treatment of tuberculous disease with chloride of zinc injections at the site of the disease, announced to the French Academy of Sciences in July of the past year, by Professor Lannelongue.[34]

It is based essentially on the simple fact that fibrinous induration is to be regarded as the natural curative process in tuberculous lesions. The power of the chloride of zinc to excite such sclerotic processes, when administered in sufficiently small quantity to avoid its more powerful escharotic action, suggested its use in the disease in question. Its action in experimental tuberculosis is thus described by M. Lannelongue and M. Achard. The anatomical elements of the tissues which it penetrates are destroyed and an enormous proliferation of embryonic cells occurs, not only at the site of the injection but for some distance around it, with infiltration of the tuberculous tissue with migratory cells to the fullest extent. M. Lannelongue suggests that the latter may destroy the bacilli through the exercise of their phagocytic function. The morbid tissue destroyed by the chloride of zinc is

slowly absorbed and disappears; the embryonic cells, on the contrary, organize with great rapidity and form firm fibrous tissue, which exists in appreciable quantity as early as the day following the injection.

Twenty-two patients were subjected to this treatment by M. Lannelongue. The list embraces two cases of pulmonary tuberculosis and twenty of suppurating and non-suppurating tuberculous disease of joints and glands. Excellent results are claimed to have been obtained in a majority of the latter. An opportunity was afforded in a case of more or less fused tuberculous glands for comparing histologically, glands which had been injected and those which had been left without treatment. Excision showed caseous material surrounded by a zone of tuberculous tissue within a fibrous sheath in each; in the injected glands, however, there was a large amount of dense fibrous tissue and firm adhesion to the investing membrane. A report of the results in the pulmonary cases was reserved until a longer period had elapsed.

While recognizing the possible utility of this method of treatment in tuberculous joint and gland disease, either as a remedial measure or as an adjunct to surgical procedures, and suggesting the desirability of more extended investigations in this direction, its application in pulmonary tuberculosis, in my judgment, should be regarded with the greatest reserve. Aside from the difficulty of introducing intra-pulmonary injections in any exact way at the site of the lesion, the extent and complexity of the morbid conditions usually present would seem to preclude the possibility of its usefulness as a method of treatment.

The technique of the method employed by M. Lannelongue is to inject two drops of a ten per cent. solution, in a number of places around the periphery of the diseased part, in cases of tuberculous joints, bones, and glands. Suppurating glands are thoroughly irrigated with sterilized water and the injections made under rigid antiseptic precautions. In cases of pulmonary tuberculosis a solution of one in forty is used for the injections.

The Treatment of Tuberculosis with Creasote, Guaiacol, and Carbonate of Guaiacol.—The literature of the treatment of phthisis pulmonalis with creasote, both by internal administration and by inhalation, is sufficiently familiar to those interested in the subject to warrant the briefest reference to it. Discovered by v. Reichenbach in 1830, it quickly secured a reputation in Germany, France, and England as a remedial agent in pulmonary disease. It, however, gradually fell into disuse, and was only rehabilitated in favor in 1877, through the admirable clinical paper of Bouchard and Gimbert on its beneficial effects in consumption.[35] Influenced by their statements, Beverley Robinson instituted its systematic use in his hospital and private practice in this city as early as 1878, and valuable papers by him have appeared from time to time since on this subject.

In Germany a series of publications by Sommerbrodt, Fraentzel, v. Brunn, Guttmann, and others, confirmatory of the results obtained by Bouchard and Gimbert, appeared in 1887 and 1888. The literature of the subject at the present time is very voluminous, and it may be said to be exceptionally favorable to the value of creasote in the treatment of pulmonary phthisis.

Varied opinions are held in regard to its mode of action, its most efficient dosage, and the best method of administration. The determination of these several points is of scientific interest as well as of practical import.

The efficacy of creasote in hindering or arresting fermentative processes in the digestive tract, so frequently present in phthisical patients, and thereby promoting appetite, digestion, and nutrition, is very generally admitted. Its ability to favorably affect appetite and to increase the digestive secretions, when given by the mouth, by locally stimulating the gastric and intestinal nerve-filaments, is also very probable. Through the promotion of a better nutrition, the beneficial effects claimed for creasote, in stimulating the resolution and absorption of the secondary inflammatory exudations in tuberculous lungs, may be explained. By its local action, antiseptic and stimulating, especially when given in the form of inhalations, a favorable influence upon the simple catarrhal processes so commonly present, is conceivable and probable. In turning our attention to any *specific* action which creasote may exercise upon the pathogenic cause of tuberculosis and its specific lesions, the results of experimental investigation properly should be considered.

Guttmann[36], as the result of test-tube experiments, which he claimed demonstrated the power of creasote, in solution of 1 to 4,000, to greatly inhibit the growth of tubercle bacilli, and in solutions of 1 to 2,000 to completely devitalize them, was led to believe that a similar specific action could be effected in the human body by the administration of sufficiently large doses of the drug. One gramme of creasote, according to his calculations, present in the circulation would suffice for this purpose. The experimental investigations very kindly undertaken for me by Dr. John Ely in the Pathological Laboratory of the College of Physicians and Surgeons, and which will be given in detail later, confirm the correctness of Guttmann's observations on the germicidal power of creasote.

Granting therefore the germicidal action of creasote *outside* of the human body, and also the possibility of administering it without injurious effects in daily doses larger than those demanded by Guttmann's hypothesis, a seemingly fatal objection to the theory of the exercise of a germicidal action in the economy, is found in very recent investigations which indicate that creasote enters at once in the blood into chemical combinations with certain contained albuminoids, combinations which are *without specific germicidal influence*. Moreover, it has been wisely said that "man is not a test-tube," and no fact appears to be more clearly proven than that the germicidal action of a drug outside of the body affords little basis for correct conclusions of its therapeutic value. Experiments on animals are necessary to determine these points.

In pursuance of this idea, numerous investigators have attempted to test the anti-bacillary power as well as other effects of creasote in tuberculosis by the treatment of animals with large doses of this drug both before and after the production of experimental tuberculous disease. I shall refer only to the very interesting experiments of Trudeau,[37] and Cornet.[38]

In Trudeau's experiments four rabbits were inoculated in the anterior chamber of the eye and in the right chest with a similar amount of pure cultures of tubercle bacilli suspended in water. Two of the rabbits were kept as "controls." Two were treated every other day with subcutaneous injections of five cubic centimetres of a ten per cent. solution of pure creasote in almond-oil. The course of the eye tuberculosis in the test-animals was daily compared with that in the "controls," and was seen to be entirely uninfluenced by the treatment. Tubercles became visible in the iris from the twelfth to the thirteenth day in both sets of animals. Iritis, cloudiness of the cornea, and general secondary inflammatory changes were noted in all the rabbits from the eighteenth to the twenty-first day, and the sight was soon lost. All were killed two months after inoculation, and the lungs of both the test and the control animals presented the lesions of advanced tuberculosis.

Cornet's experiments were as follows: Seven strong guinea-pigs were treated with creasote, introduced into the stomach by means of a tube, in doses equivalent for the body weight of a man to rather more than two grammes daily, for a period varying from one to two months. At the expiration of this interval they with four control-animals were either inoculated with or were compelled to inhale finely atomized pure cultures of tubercle bacilli, the creasote treatment being continued in the test-animals. A single test guinea-pig died of pneumonia ten days after inoculation. The remaining six died respectively thirty, thirty-two, thirty-three, forty-three,

seventy-seven, and eighty-four days after infection. Two of the control-animals were killed on the thirty-second and forty-third day after infection; the two remaining died on the sixty-first and eighty-fourth day after inoculation. All the animals, both test and control, presented the characteristic lesions of tuberculosis, and very little if any appreciable difference in the appearance, the degree, or the distribution of these could be detected in the two sets.

Experimental investigations, therefore, show in the most positive manner that creasote, administered even in heroic doses, is incapable either of preventing the development of experimental tuberculosis or of arresting its progress.

The theory of Bouchard, Gimbert, Jaccoud, and others, that creasote promotes connective-tissue growth, by means of which recovery in tuberculous disease is favored, also is not borne out by experimental studies in animals.

The explanation of any favorable influence of creasote on sclerotic processes which *clinical* observation may indicate, should seemingly be sought in the improved nutrition which obtains through its use rather than by the exercise of any specific action.

Guaiacol, obtained by fractional distillation of beech wood-tar creasote, and constituting sixty to ninety per cent. of the latter, was suggested by Sahli,[39] as early as 1887, as a substitute for creasote in the treatment of tuberculous disease. It represents the active principle of creasote, and may be substituted appropriately for it. As prepared in the various laboratories, it probably is not freed from all impurities.

Owing to this fact, very lately Seifert and Hoelscher[40] have proposed the use of the carbonate of guaiacol. Carbonate of guaiacol possesses the advantages over creasote and guaiacol of being a simple, definite, and crystalline substance which can be obtained chemically pure. It is a neutral salt, and is tasteless as well as odorless. It does not produce digestive disturbances, it is indifferent to the gastric secretion, and decomposes in the intestine into guaiacol and carbonic acid.

Many of the above characteristics of this salt have been demonstrated in its use in St. Luke's Hospital. Seifert and Hoelscher, as the result of experimental studies with guaiacol carbonate, have advanced a new and interesting theory of the mode of action of the creasote preparations in tuberculous disease. The basis of their theory apparently rests on the fact that experiments on dogs show that creasote and guaiacol do not circulate in a free state in the blood, and that they are eliminated by the kidneys in the form of the salts of ethyl sulphuric acid (aetherschwefelsäure). They argue that during absorption, the active principle of creasote allies itself with the albuminoids in the blood, and specifically through the agency of the sulphur contained in the albumin molecule. The blood of tuberculous patients contains in addition to normal albumin other albuminoid substances arising from the disease process, *e.g.*, the products of the tubercle bacillus. These substances constitute unstable combinations, prone to cause or undergo chemical processes, which act poisonously. The toxic albuminoids engendered by the disease are chiefly responsible for the fever, night-sweats, etc. The guaiacol, by allying itself with them, renders them stable and therefore non-toxic. The chemical combinations effected by the guaiacol are *without germicidal influence*, and the favorable results obtained through the use of the creasote preparations in tuberculous disease, therefore should be regarded as due in a large measure to their influence in assisting in the elimination of the toxic products of the specific disease process.

Seifert's and Hoelscher's theory in no respect militates against other favorable influences which have been ascribed to the creasote preparations, such as the probable direct stimulation of the appetite, and thereby improved nutrition, etc. The observations thus far made in St. Luke's Hospital in the use of guaiacol carbonate, lead me to believe that it may be substituted very favorably for both creasote and guaiacol.

Investigations in St. Luke's Hospital, with Modified Tuberculin, Creasote, Guaiacol, and Carbonate of Guaiacol.—During the past winter sixty-five cases of pulmonary tuberculosis have been under my care continuously in the wards of St. Luke's Hospital. Many of these were cases of very advanced disease, without the possibility of recovery, and the treatment consisted merely in attempts to ameliorate the most distressing symptoms. Nineteen of the remaining cases were selected for treatment, respectively, with Hunter's modifications of Koch's tuberculin, with subcutaneous injections of guaiacol, and with creasote by the mouth. It was my desire not so much to test the comparative merits of different methods of treatment, as to corroborate, or otherwise, Cheyne's and Hunter's observations, and to determine both the practicability of employing a very large daily dosage of creasote and any advantages this method might possess over its use in smaller quantities. Seven cases of well marked tuberculosis are embraced in the group treated with Hunter's modified tuberculin. The details of the histories of these patients, and the results of treatment, are given in a tabulated form for convenience in study. It will be seen that three cases have been under treatment for three months, the remainder for nearly two months. Physical examination in two of the former cases indicates no appreciable change in the pulmonary lesions during treatment. In the third case, the improvement in the signs of disease, and in all other respects, has been most marked. Physical examination indicates not only the dryness of the cavity, but also its very evident contraction, as well as a diminution in the degree of the contiguous disease process. In the four remaining cases, there has been no improvement in one; in one, improvement has been marked; in one, it has been distinct, though less marked; and in one case an arrest of the disease, at least temporarily, has occurred. It will be observed in a study of the tabulated report, that by improvement is meant a marked diminution in the physical signs of disease.

Case VII. is certainly an example of arrested phthisis. This is of such rare occurrence in pulmonary tuberculosis of this degree, under conditions which commonly prevail in large city hospitals, as to be particularly noteworthy. A very distinct impression has been made on my mind, in observing from day to day the cases treated with modified tuberculin, that its stimulation of the nutritive processes is not so marked as its effect upon the specific lesions. Creasote, on the other hand, has seemed to me to possess the former quality in a greater degree. To meet possible criticism, all the above cases have received no other treatment than tuberculin, beyond the administration of cod-liver oil, and, from time to time, various ferruginous preparations.

The exact mode of preparation of the modifications used is given in a note.* The rule of dosage was to give 0.002 gm. for the initial inoculation, and to increase by 0.002 gm. daily. The rule also was made not to increase the dose if any elevation of temperature followed inoculation. With the modifications B. and C.B., appreciable

* Method of preparation of Hunter's modifications: Modification "B.," 1 c.c. of tuberculin, 5 c.c. distilled water, saturation with preferably large crystals of ammonium sulphate for twenty four hours in the cold, the precipitate filtered off and freed so far as possible from any crystals of ammonium sulphate, placed in dyaliizer, and dyalized just so long and no longer in running water, and then in distilled water, until all trace of ammonium sulphate has disappeared. Crystals of thymol added to the solution to prevent any putrefactive change; the solution then made up to such bulk that 10 c.c. shall correspond to each c.c. of tuberculin employed. (Title, B., ten per cent.)

Modification "C.B.," 2 c.c. of tuberculin dropped into 20 c.c. absolute alcohol; heavy precipitate filtered off in a quarter of an hour; filtrate evaporated over water-bath at temperature preferably not exceeding 40 C., and just sufficiently long to drive off all alcohol; residue taken up in 12 c.c. distilled water; placed in dyalizer and dyalized for two hours in running stream of water. Quantity made up to 20 c.c., including 2 c.c. of pure glycerine used for preservative purposes. A few crystals of thymol added. (Title, C.B., ten per cent.)

The above modifications were prepared for me in the Chemical Laboratory of the College of Physicians and Surgeons.

reactions did not occur in the above cases. In a single case not reported in the following table, treated with C.B, a rise of temperature followed an inoculation of 0.008 gm., and an acute catarrhal process was developed at the apex of one lung. At the expiration of the tenth day, defervescence occurred and no further ill effect has followed. For this reason modification B. has been used in all other cases but one. Trudeau has also adopted, I believe, modification B. as the preferable one. Through the absence of all reaction and discomfort attending the use of B., all patients treated with it have been able to be continuously about the wards and out-of-doors. Only the usual very inexact method for determining the number of bacilli in the sputum was used. Repeated examinations were made, and they were found in all.

The number of cases treated with modified tuberculin, while much too small to permit the expression of a positive opinion of its power to exercise a specific remedial action, is large enough to indicate in the strongest manner the desirability of continued investigations of its *apparently specifically beneficial effects*.

My desire to test the practicability of employing a very large daily dosage of the creasote preparations, and to determine, if possible, any advantage which this method might possess over their use in smaller quantities, has been fulfilled in a measure. Several of the patients selected for this treatment presented in a well marked degree many of the symptoms, viz., hectic, sweats, etc., attributed to the toxic influence of the *products* of the bacillus, and were therefore well adapted to test the effect of creasote upon such manifestations. It will be seen in the tabulated record that seven cases have been treated with subcutaneous injections of guaiacol, rapidly pushed to a daily dosage of one gramme, and five cases with creasote by the mouth, also rapidly increased to six grammes daily.

In four of the former cases there has been little, if any, change in the physical signs of disease. In one of these, however, the general condition has greatly improved and there has been a gain in weight of eight pounds. In one, the weight has decreased by one and three-quarter pounds; in one, there has been a loss of four pounds; in one, the weight has remained stationary.

In two of these cases the daily sputum has slightly increased in amount; in two, it has slightly diminished. In the three remaining cases, there has been a progressive increase of the pulmonary lesions. No influence upon hectic when present has been observed. Night-sweats, however, have been affected favorably. In a single case suffering from chronic diffuse nephritis (confirmed by autopsy) a marked increase in the albuminuria was observed when a daily dosage of one gramme was reached.

The treatment was then discontinued and the albuminuria gradually diminished. In no other case, treated either with guaiacol or creasote, has any trace of albumin appeared in the urine, in examinations made every other day. In a single case, when the maximum dose of guaiacol was reached, the urine became dark in color and very similar in appearance to urine containing carbolic acid products

Dr. Ely's report on the enumeration of tubercle bacilli in the daily sputum of several patients treated with guaiacol contains observations of interest and practical import. It indicates the possibility of incorrect conclusions even from the best method at our command for this purpose; also the absence of bacilli, from time to time, in the sputum of patients suffering from grave pulmonary tuberculosis.

In Cases II. and IV., where there has been no apparent increase in the lesions, and the general condition has remained stationary, the number of bacilli has greatly diminished.

In Case VII., in which the area of disease has slightly increased, and the general condition has deteriorated, the bacilli have greatly increased in number.

In the cases treated with creasote there has been no appreciable difference in the physical signs of disease up to the present date, in two. In these there has been a gain of one pound and a loss of three pounds, respectively.

In the three remaining cases there has been a progressive increase of the lesions. The effect of a very large daily dosage of creasote upon hectic and sweats, corresponds to that noted in the use of guaiacol. Entire tolerance of six grammes (over one and one-half drachms) of creasote was exhibited by three of the five patients. One complained of slight gastric discomfort when a daily dosage of five grammes was reached, and one patient who had suffered from occasional nausea and vomiting previous to the administration of creasote, believed that these symptoms were increased by it. Several other patients at present in my wards are taking four to six grammes of guaiacol daily, without gastric or intestinal discomfort.

Carbonate of guaiacol has been used, so far as its supply permitted, and aside from the advantage of being tasteless and odorless, and only being decomposed by the intestinal secretions, it has seemed to me to very positively stimulate appetite.

The clinical conclusions which I have formed from a careful study of these cases are: That both creasote and guaiacol in certain forms can be given in very large doses with entire tolerance and without injurious effects; that such dosage apparently possesses no advantages over a much smaller one, and that it has no greater effect upon hectic and night-sweats; that subcutaneous injections of the drug possess no advantages over administration by the mouth; that whatever beneficial influence creasote may exert in pulmonary tuberculosis can be effected with a comparatively small dosage and that favorable results can be expected only by its continuous and prolonged employment.

Dr. Ely's reports of his investigations on the germicidal action of creasote on the tubercle bacillus outside of the human body, and on the enumeration of bacilli in the daily sputum of patients, treated with guaiacol, are appended.

For valuable assistance rendered me in my investigations, I desire to express my thanks to Drs. John Ely and Robert J. Devlin and to the gentlemen of the House Staff of St. Luke's Hospital, Drs. Hollis, Rogers, Bunce, and Tuttle.*

Dr. Ely's Report on the Germicidal Action of Creasote Outside of the Human Body.—Shortly after the revival of interest in creasote as a therapeutic agent in tuberculosis the question arose as to the manner in which its beneficial effect was produced. Its general preservative and anti-fermentative properties had long been recognized and made use of in the arts, and the possibility of a similar inhibiting or germicidal action upon the specific germs of tuberculosis at once suggested itself. With a view to the solution of this problem Guttmann undertook a more definite determination of its germicidal action.

In his experiments nutrient gelatine was impregnated with creasote in proportions varying from 1 to 500, to 1 to 8,000. Into this seventeen different species of bacteria, thirteen of them pathogenic, were inoculated, at the same time similarly inoculated tubes of ordinary nutrient gelatine serving as controls. The inhibiting action of the creasote was found to vary considerably with the different species, but in general a creasote content of 1 to 2,000 was found sufficient to prevent growth. The plan of experiment received slight modification in the case of the tubercle bacillus, blood-serum being used as the nutrient medium, and the cultures, after inoculation, being placed in the thermostat at a temperature of 37° C. After several weeks, examination showed a meagre growth in the tubes

* Creasote was administered without exception, in the form of what are known as the "Enteric Pills" of a well-known manufacturer. The nature of their protecting envelope I am ignorant of. Personal investigation of the effect of an artificial gastric juice upon the envelope showed that it was partially dissolved after one hour.

which had contained creasote in the proportion of 1 to 16,000; none in the others.

Since these experiments of Guttmann, so far as I am aware, stand quite alone, it has been thought avisable to repeat them in so far as they relate to the tubercle bacillus, but in slightly modified form. Instead of blood-serum, glycerine-bouillon and glycerine-agar have been used as nutrient media, both of which have shown themselves particularly well adapted to the growth of the tubercle bacillus; and an aqueous solution of guaiacol, the principal ingredient of creasote, has been substituted for the alcoholic solution of creasote employed by Gutt-

Treatment with Subcutaneous Injections of Hunter's Modified Tuberculin.

No. of case, sex, and age.	Patient's history and physical examination at beginning of treatment.	Patient's weight, daily sputum, inoculation used, date when begun.	Duration of treatment, weight, and sputum, to date.	Physical examination at present date.
I. Male, 42 years.	Profuse hæmoptysis 5 years ago; pleurisy 3 years ago; night-sweats and cough since, with loss of 40 lbs. in weight. Physical signs: Slight retraction beneath right clavicle. Evidence of cavity in first interspace; also very abundant largish moist râles at this site. Abundant subcrepitation from first space to base. Posteriorly, same side, abundant subcrepitation, with larger râles, over supraspinous fossa. Abundant subcrepitation over whole of scapular region. Patient apyretic.	Jan. 13, 1892, weight, 134 lbs. Sputum, ℥iv., daily average. "B." 0.002 gm., to increase by 0.002 gm. daily.	April 25, 1892, weight, 141¼ lbs. Sputum, ℥j¼, daily average. "B." 0.198 gm., to increase by 0.002 gm. daily.	April 25th.—Physical signs: Marked retraction, directly beneath right clavicle. Signs of cavity distinctly less marked, and it is apparently nearly dry. Scanty subcrepitation in second space; below this point, no adventitious sounds present. Posteriorly, adventitious sounds absent over supra-spinous fossa and marked diminution of subcrepitation over scapular region. Patient apyretic; no night-sweats. Very marked improvement.
II. Male, 47 years.	History of 18 months; sputum occasionally tinged with blood; absence of night-sweats. Physical signs: Consolidation without crepitation over first and second right-spaces and over supraspinous fossa. Posteriorly, subcrepitation over interscapular region Left lung, feeble respiratory murmur, with scanty subcrepitation beneath clavicle and over supraspinous fossa. Evening temperature occasionally 100° F.	Jan. 14, 1892, weight, 122 lbs. Sputum, ℥j., daily average. "C B." 0.002 gm., to increase by 0.002 gm. daily.	April 25, 1892, weight, 125 lbs. Sputum, ℥j., daily average. "C.B." 0.092 gm., to increase by 0.002 gm. daily.	April 25th.—Physical signs: Practically the same as on first examination. Evening temperature occasionally 100° F. Condition stationary.
III. Female, 32 years.	History of cough and occasional hæmorrhage for past 2 years. Physical signs: Dulness, with rather abundant subcrepitation in first right interspace; scanty subcrepitation in second space. Dulness, with moderate subcrepitation posteriorly, over supraspinous fossa and scapular region. Patient apyretic.	Jan. 17, 1892, weight, 105 lbs. Sputum, ℥j., daily average, "C.B." 0.002 gm., to increase by 0.002 gm. daily.	April 21, 1892, weight, 107 lbs. Sputum, ℥j¼, daily average. "C.B." 0.176 gm., to increase by 0.002 gm. daily.	April 21st.—Physical signs: Dulness with scanty subcrepitation in first space; absent in second. Dulness with scanty subcrepitation over supra-spinous fossa and scapular region. Little appreciable difference from first examination. Patient apyretic. Condition stationary.
IV. Male, 50 years.	Cough for past year; gradual loss of flesh and strength. Physical signs: Impairment of resonance over upper half of left chest, anteriorly, with fairly abundant subcrepitation over same. Posteriorly, impairment of resonance over upper half of left chest, with abundant subcrepitation over supraspinous fossa and scanty in areas over scapular region. Patient apyretic.	March 2, 1892, weight, 144 lbs. Sputum, ℥j., daily average. "B." 0.002 gm., to increase by 0.002 gm. daily.	April 25, 1892, weight, 148½ lbs. Sputum, less than ℥j, daily average. "B." 0.110 gm., to increase by 0.002 gm. daily.	April 25th.—Physical signs: Little appreciable difference in resonance over upper half of left chest since first examination. Crepitation has almost wholly disappeared anteriorly, and is practically absent posteriorly. Patient apyretic. Marked improvement.
V. Male, 32 years.	Hæmorrhage 5 years ago and another 3 years ago, very profuse. Since latter, unable to work, and has lost 40 lbs. in weight. Treated with tuberculin in Presbyterian Hospital a year ago, and apparently improved temporarily. Physical signs: Diffuse infiltration upper lobes of both lungs, with abundant subcrepitation at apices and scantier over remainder of affected regions. Most marked, right apex; occasional night-sweats. Patient apyretic.	March 2, 1892, weight, 123 lbs. Sputum, ℥j., daily average. "B." 0.002 gm., to increase by 0.002 gm. daily.	April 25, 1892, weight, 119 lbs. Sputum, ℥j., daily average. "B." 0.078 gm., to increase by 0.002 gm. daily.	April 25th.—Physical signs: No appreciable difference from first examination. Occasional night-sweats. Patient apyretic. Condition stationary.
VI. Male, 33 years.	Cough for 3 months; no hæmoptysis, no night-sweats. Physical signs: Impairment of resonance, with loss of vesicular respiration over right infraclavicular region. Abundant subcrepitation in second and third spaces. Similar signs over whole left chest anteriorly; in less degree also over left supraspinous fossa and scapular region. Slight pyrexia; evening temperature, 100–100.2° F.	March 3, 1892, treatment begun March 21st, weight, 132 lbs. Sputum, ℥ss., daily average. "B." 0.002 gm., to increase by 0.002 gm. daily.	April 25, 1892, weight, 135 lbs. Sputum none, "B." 0.100 gm., to increase by 0.002 gm. daily.	April 25th.—No appreciable difference in impairment of resonance over affected regions. Subcrepitation scanty at present over right chest, and absent over supraspinous fossa and scapular region, left. Anteriorly, same lung, no appreciable difference from first examination. Patient apyretic since March 18th. Improvement.
VII. Male, 41 years.	Cough for 6 months; no hæmoptysis, no night-sweats; gradual loss of flesh. Physical signs: Impairment of resonance, sligtly prolonged and high pitched expiration, with abundant subcrepitation in first two spaces, left; scanty, fine crepitation below. Same signs over supraspinous fossa as beneath clavicle; over upper half scapular region, scanty crepitation after cough. Slight pyrexia; occasional evening temperature, 100° F.	March 3, 1892, weight, 135 lbs. Sputum, ℥ss., daily average. "B." 0.002 gm., to increase by 0.002 gm. daily.	April 18, 1892, weight, 135 lbs. Sputum, none. Discharged, through desire and ability to go to work.	April 25th.—Impairment of resonance over first two spaces. Respiration feeble, but expiration not prolonged or increased in pitch. Entire absence of all adventitious sounds over whole of left chest, anteriorly and posteriorly. Patient continuously apyretic since March 18th. Disease at present arrested.

Treatment with Subcutaneous Injections of Guaiacol Rapidly Increased.

No. of case, sex, and age.	Patient's history and physical examination at beginning of treatment.	Patient's weight, daily average of sputum (℥) when guaiacol ♏ j., increasing ♏ j. daily, was begun; date.	Duration of treatment, weight, and sputum, to date.	Physical examination at present date.
I. Female, 17 years.	Cough for 10 months; progressive loss of flesh and strength; no hæmoptysis; moderate night-sweats. Physical signs: Excavation at right apex anteriorly, with consolidation below; posteriorly, same lung, consolidation with numerous large râles and abundant subcrepitation over whole of scapular region, below fine crepitation. Left, anteriorly, moderate consolidation at apex, without crepitation. Advanced laryngeal disease. Marked hectic; evening temperature, 102–103° F.	Weight, Feb. 27, 1892, 70¼ lbs. Average daily sputum, ℥ ss.–℥ j. Guaiacol, 0.05 gm. daily, to increase 0.05 gm. daily to 1 gm.	March 20, 1892, 71 lbs. Average daily sputum, ℥ j.–℥ ij. Guaiacol, 1 gm. reached to-day; discontinued.	March 20th.—Physical signs: Progressive increase of lesions; night-sweats. Marked hectic; evening temperature, 102–103° F.
II. Female, 30 years.	Hæmoptysis 3 years ago; present history of cough, 3 months; progressive loss of flesh and strength; no night-sweats. Physical signs: Dulness, prolonged and high-pitched expiration over left infraclavicular region, with very abundant subcrepitation. Same signs posteriorly over upper half of left lung. Right, similar signs, less in degree, anteriorly and posteriorly over upper half. Slight pyrexia; evening temperature, 100° F.	Weight, Feb. 27, 1892, 91¼ lbs. Average daily sputum, ℥ j. Guaiacol, 0.05 gm. daily, to increase 0.05 gm. daily to 1 gm.	April 25, 1892, 91½ lbs. Average daily sputum, ℥ j.–℥ ij. Guaiacol, 1 gm. daily for 37 days.	April 25th.—Physical signs: Little appreciable difference from first examination, except subcrepitation now heard over whole left lung posteriorly. No night-sweats. Slight evening temperature.
III. Female, 24 years.	Pleurisy, right side, 3 years ago. Empyema same side 1 year ago, exsection of rib; cough and frequent hæmoptysis since; night-sweats. Physical signs: Large antrum in first right space, nearly dry. Moderate consolidation, without crepitation, in second space. Consolidation, apex, same lung, posteriorly, without crepitation. Patient apyretic.	Weight, Feb. 27, 1892, 135 lbs. Average daily sputum ℥ ij.–℥ ss. Guaiacol, 0.05 gm. daily, to increase 0.05 gm. daily to 1 gm.	April 25, 1892, 141 lbs. Average daily sputum, 0–℥ ss. Guaiacol, 1 gm. daily for 37 days.	April 25th.—Physical signs: Anteriorly, no appreciable difference from first examination; posteriorly, moderate subcrepitation at apex and over upper half of scapular region. Patient apyretic; occasional night-sweats. Marked improvement in general condition.
IV. Female, 44 years.	Pneumonia, 3 years ago; cough since; no hæmoptysis, no night-sweats at present. Physical signs: Consolidation, with fairly abundant subcrepitation at both apices. Subcrepitation also present over upper half right scapular and upper third left scapular regions. Slight pyrexia; occasional evening temperature, 100.2° F.	Weight, Feb. 28, 1892, 91¾ lbs. Average daily sputum, ℥ ss.–℥ j. Guaiacol, 0.05 gm. daily, to increase 0.05 gm. daily to 1 gm.	April 25, 1892, 90 lbs. Average daily sputum, ℥ ss. Guaiacol, 1 gm. daily for 37 days.	April 25th.—Physical signs: No appreciable difference from first examination; no night-sweats. Occasional evening temperature, 100.2–100.3° F.
V. Female, 32 years.	Grippe a year ago; cough since; no hæmoptysis; profuse night-sweats. Physical signs: Areas of infiltration throughout upper lobe, right lung, with abundant subcrepitation. Areas of infiltration upper lobe, left lung, with abundant subcrepitation and evidence of beginning excavation at apex. Hectic; evening temperature, 101–102° F.	Feb. 28, 1892, 72 lbs. Sputum, ℥ ij.–iv., daily average. Guaiacol, 0.05 gm. daily, increasing 0.05 gm. daily. March 12, 1892, 0.60 gm. Weight, 72 lbs.; sputum, ℥ ij.–iv.	March 15, 1892, guaiacol by mouth, ♏ x.; ♏ iv. daily average. March 24th, ♏ iij. daily in pill, not increasing. April 1, 1892, weight, 64 lbs. April 6, 1892, sputum, ℥ iv.–v.	April 1st.—Physical signs: Progressive increase of lesions; moderate sweats. Treatment apparently some effect on sweats, none on fever. Died April 7, 1892.
VI. Female, 46 years.	History of 10 months; a single hæmoptysis; night-sweats almost continuously. Physical signs: Large antrum, apex left lung, with impaired resonance and abundant subcrepitation to base anteriorly. Posteriorly, areas of subcrepitation to base. Beginning disease at right apex. Hectic; evening temperature, 101–102° F.	Feb. 28, 1892, 95⅛ lbs. Sputum, ℥ j.–ij., daily average. Guaiacol, 0.05 gm. daily, increasing 0.05 gm. daily. March 9, 1892, 0.45 gm. Weight, 93¾ lbs.; sputum, ℥ ij.–iij.	Treatment discontinued before maximum dose reached; no further treatment. March 24, 1892, weight, 96¼ lbs. March 31, sputum, ℥ ss.–℥ ij.	March 10th.—Progressive increase of lesions. Treatment apparently some effect on night-sweats, none on fever. Died April 1, 1892.
VII. Male, 31 years.	Typical history since last November; several hæmoptyses; no night-sweats. Physical signs: Feeble respiratory murmur, with abundant subcrepitation over whole of right lung, anteriorly, and upper half of scapular region. Similar signs in slightly less degree over upper lobe left lung, anteriorly and posteriorly. Pyrexia; evening temperature, 101–102° F.	March 2, 1892, 92 lbs. Sputum, ℥ vij.–xjss. daily average. Guaiacol, 0.05 gm. daily, increasing 0.05 gm. daily. March 21, 1892, 1 gm. for 2 days. Weight, 88½ lbs., sputum, ℥ vij.	March 22, 1891, guaiacol carbonate, gr. vj. daily by mouth. April 12, 1892, weight, 86¼ lbs. Sputum, ℥ iij.; treatment stopped. April 19, 1892, guaiacol pill, ♏ vj. daily, increasing, ♏ iij. April 25, ♏ xxvij.; weight, 88 lbs.; sputum, ℥ iij.	April 25th.—Physical signs: Very similar to those of first examination, except subcrepitation heard over whole of left lung anteriorly and posteriorly; no night-sweats; pyrexia. Evening temperature, 100–101° F. General condition worse.

mann in the preparation of his media.* These media were impregnated with guaiacol in the proportions of 1 to 1,000, 1 to 2,000, 1 to 3,000, and 1 to 4,000, and into them were introduced particles of a rapidly-growing culture of the tubercle bacillus, other media, not containing guaiacol, being at the same time inoculated as controls. All were then sealed and placed in the thermostat at 37° C. At the end of seven weeks they were examined and the records tabulated below noted. It may be permissible to state here that every slightest indication of growth was carefully searched for and that no record is made except where all the conditions necessary to the growth of the tubercle bacilli were observed, so that the

Control, four flasks.	1 to 1,000, two flasks.	1 to 2,000, two flasks.	1 to 3,000, three flasks.	1 to 4,000, two flasks.
1. Moderate growth, not spreading much, but heaping.	1. No growth.	1. No growth.	1. No growth.	1. Apparently slight heaping up, thought to indicate very slow growth.
2. Luxuriant growth, overgrowing whole surface of the bouillon.	2. No growth.	2. No growth.	2. No growth.	2. Slight heaping, though somewhat questionable.
3. Luxuriant growth, overgrowing whole surface of the bouillon.			3. No growth.	
4. Moderate growth, heaping.				

SERIES B.—*Glycerine Agar.—Inoculated March* 11, 1892; *Examined April* 29, 1892.

Control, four tubes.	1 to 1,000, five tubes.	1 to 2,000, five tubes.	1 to 3,000, five tubes.	1 to 4,000, five tubes.
1. Very luxuriant growth, heaping and spreading.	1. No growth.	1. No growth.	1. No growth.	1. No growth.
2. Abundant growth, heaping and spreading.	2. No growth.	2. No growth.	2. No growth.	2. Very slight heaping and cloudiness at edges, as if growing sluggishly.
3. Moderate growth.	3. No growth.	3. No growth.	3. No growth.	3. Abundant growth.
4. Moderate growth.	4. No growth.	4. No growth.	4. No growth.	4. Very slight heaping; no apparent spreading.
	5. No growth.	5. No growth.	5. No growth.	5. Slight heaping and cloudiness at edges as if slowly spreading.

Results of the Determination of the Actual Number of Tubercle Bacilli in Twenty-four Hours' Sputum, by Nuttall's Method.

Case.	Date.	Quantity of sputum in twenty-four hours.	Number of tubercle bacilli in twenty-four hours' sputum.
I.	Feb. 24, 1892...	9 fluidrachms.	227,684,401.
II.	Feb. 24, 1892...	12 fluidrachms..	7,798,791.
	March 23, 1892..	9 fluidrachms..	4,189,915.
	April 6, 1892...	1 fluidounce...	1,946,657.
	April 29, 1892..	3 fluidrachms..	380,828.
III.	Feb. 22, 1892...	1 fluidrachm ..	579,792.
	March 23, 1892..	3 fluidrachms..	About one hundred fields carefully gone over without finding any bacillus. Whole drop then examined systematically and still none found. Stain good.
	April 23, 1892..	4 fluidrachms..	6,858,690.
IV.	Feb. 26, 1892...	6 drachms....	7,707,033.
	March 23, 1892..	6 drachms....	274,246.
	April 6, 1892...	4 drachms....	207,149.
	April 29, 1892..	2 drachms....	270,228.
VII.	March 17, 1892..	.....	One hundred fields carefully gone over; no bacillus. Whole drop; no bacillus. Stain good. A second cover of same examined with same result.
	March 28, 1892..	10 ounces 6 drachms	One hundred fields searched as above no bacillus. Duplicate cover gives same result.
	April 6, 1892 ..	11 ounces 4 drachms	1,307,395.
	April 29, 1892..	11 ounces.....	2,915,976.

Dr. Ely's Report on the Enumeration of Bacilli in the Daily Sputum of Patients Treated with Subcutaneous Injections of Guaiacol.—While fully recognizing the illusive nature of conclusions as to the value of therapeutic agents based upon periodical determinations of the number of tubercle bacilli in the sputum, it has been thought desirable to make such determinations in a number of the cases treated with creasote and guaiacol.

The method employed for this purpose has been that recommended by Nuttall, the details of which are to be found in the *Bulletin of the Johns Hopkins Hospital*, vol. ii., No. 13, May to June, 1891.

Although this method is unquestionably the most accurate thus far proposed, it is nevertheless subject to great error, and the results are liable to be particularly misleading in cases in which the amount of expectoration is large and the number of bacilli small. Case VII., tabulated above, may be referred to as an example. About eleven ounces of sputum were eliminated daily. This was so viscid that its disintegration necessitated the addition of considerably more than an equal bulk of potash and water, so that the total amount after dilution came to be 700 c.c. Since the dropper used delivers about one hundred drops to the cubic centimetre, the content of each drop (in this particular case), must be multiplied by seventy thousand in estimating the total number of bacilli eliminated in twenty four hours, and of course, any error in the determination of the number of bacilli to the drop is similarly multiplied. And when there are only a few bacilli to each drop, all may be overlooked in counting fifty fields, or, on the other hand, a disproportionate number may chance to be seen. Thus in Case VII., while the majority of the fields contained no bacilli, one had three. A discrepancy of one hundred thousand or so is a matter of small import when many millions of bacilli are present, but may be very misleading when there are only a few hundred thousand.

THE INSANE IN EGYPT.

By FREDERICK PETERSON, M.D.,

NEW YORK.

It is well known that the population of the State of New York is in the neighborhood of six million, and that it has some sixteen thousand insane under public care. New York City and Brooklyn together, with two million inhabitants, have asylums which accommodate at present over seven thousand three hundred insane. These statistics are given as preliminary to a description of the conditions in Egypt, where I have been spending the winter. When we turn from a contemplation of the foregoing facts in reference to one of the newest countries in the world to Egypt, which if not the oldest, can yet boast of a civilization sixty centuries ago, we are struck by a remarkable difference. Egypt too has six million of inhabitants, and, according to the usual ratio of cases of insanity to population, she should have some twenty thousand insane, or even if she were a much favored nation in this respect, there should still be ten thousand cases within her borders. But the fact before us is that the whole country possesses but one lunatic asylum, located at Cairo, and its daily aggregate of patients rarely exceeds two hundred and fifty. At my visits in December, 1891, and March, 1892, there were two hundred and forty eight.

It is very difficult to ascertain the reasons for this extraordinary deficiency. It is true that the Koran teaches that the insane and particularly idiots are holy men, that their souls having been taken to heaven, their bodies are without mental guidance. Therefore the Mussulmans do not look upon the insane as sick and requiring medical supervision, but as the happy recipients of a direct blessing from heaven. This is quite different from the early Christian belief in possession by devils. Apoplexy is also regarded by Mohammedans as a visitation from God, and is not treated medically. It is also true that the Egyptians, unacquainted with hospitals, object to them, and prefer to care for their sick in their own homes or villages. While, therefore, it is not infrequent to meet with idiots and wildly insane people in the streets of Cairo and other cities and towns, and while I observed several at various times in places in Upper and Lower Egypt, still, taking all this into consideration, it would seem to be impossible to account for the extraordinarily small number of insane in the country on any other hypothesis than that the percentage of insane is vastly lower here than anywhere else in the world.

I made inquiries of native physicians at various points along the Nile, such as Benisooef, Minieh, and the like, with populations varying from 10,000 to 30,000. They said they seldom or never saw insane people in their practice, since they were not considered patients. Of course if a man becomes dangerous or homicidal, which is extremely unusual, he is taken into custody by the civil authorities and sent to the Cairo asylum. Inquiries, too, in the villages gave me little additional information, although I would hear of the existence of imbeciles or mild types of insanity in some of these places. It is often the custom to provide them, when at all troublesome, with places to sleep in the desert near at hand and there feed them, a sort of colonization system for which the desert offers exceptional advantages. There is no one to annoy there, nothing to destroy or hurt one's self with, and one can be as noisy as one pleases with perfect immunity.

To return now to the asylum at Cairo, it is of comparatively recent origin. Although Egypt has thrice been the medical centre of the whole world (once in the Twelfth Dynasty, again in the time of Ptolemy Energetes, and lastly under the Arabian school), we do not seem to find evidence of the existence of an asylum for lunatics before about 1280 A.D., at which time the Mameluke Kalaoon founded that at Cairo. The patients at that time seem to have been well treated. Harmonious music was employed for the sleepless, and this seems to be a very early use of music as a therapeutic agent. Story-telling (a common custom among the Egyptians), dancing, and light comedy were features of the treatment. Subsequently the institution degenerated. Napoleon in 1800 made some improvements. Many of the patients were then in chains. In 1877 Dr. A. R. Urquhart visited them in an abandoned warehouse across the Nile from Cairo, and wrote a description of their condition in the *Journal of Mental Science* for April, 1879. The following are excerpts from his article:

"Amid all the wonders of Cairo, amid the mosques and the bazaars, amid the gayeties of the oriental Paris sprung up under the fostering care of the Khedive, amid the gigantic relics of that wondrous civilization of ancient Egypt, there is no more melancholy, degrading fact than their common madhouse. . . . Doré with pencil among the noisome alleys of London, Dickens with pen in the horrors of the Fleet, have made us familiar with miseries and loathsomeness that would be comfort and cleanliness to *Les Miserables* of Cairo. Sprawling on the uneven, hard-trodden floor of the courtyard, furiously treading its limited space, crouching in its filthy recesses, or surrounding us with entreaties and menaces, were some two hundred hopeless lunatics in various stages of nudity. The sun was beating down fiercely, and the stench of the place was almost unbearable."

He saw six or eight perfectly naked in one room whose walls were smeared with filth and steaming with urine; and one loaded down with chains.

Dr. Tuke made a somewhat similar report of a visit, in an article in the same journal of the same date.

In 1880 the warehouse on the Nile was given up and the asylum transferred to quarters which it now occupies on the edge of the desert two or three miles out of Cairo. The present building was once the apartment of the black slave girls, being the remains of a royal palace which was burned in 1878. Here it was that Dr. F. M. Sandwith visited the lunatics in 1883, and was shocked at the state in which he found them. Filth, hunger, chains, nakedness, and the whip were met on every side. The following year Dr. Sandwith and a native pacha were made chiefs of the Sanitary Department of Egypt. Under Dr. Sandwith's care and attention, the asylum became transformed. He was their Pinel, striking off the chains of the poor creatures, and opening up a new era in their miserable lives. One chain was used to fasten the ankles to the floor, and others were used to chain the wrists to heavy staples in the wall near the floor. Thus the patient was obliged to keep a more or less recumbent position, and a bare board was provided for lying upon. There were no official visitors, and the chief doctor at the time was an Italian Jew without a diploma. There was no responsibility anywhere. Dr. Sandwith improved the severe system of the building, which was in a horrible state, struck off the chains of the patients, put in an intelligent young doctor with a Paris diploma, together with good male and female attendants, clerk, storekeeper, gardener, carpenter, matting maker, and the like, organized *fêtes*, began gardens, which are now very pretty court-yards, gave them better-lighted and better-ventilated wards and new bath-rooms, and provided a better regimen and sufficient clothing. All of the reforms carried out were described in a paper in the *Journal of Mental Science* for January, 1889, by Dr. Sandwith. I had the pleasure of making two visits to the institution, the last time in the company of Dr. Sandwith. The first time I came unexpectedly. On both occasions I was received by Dr. Emin Bedr, who is in charge, with great cordiality, and shown everything good and bad about the asylum. Dr. Bedr is a Paris graduate and has two assistants, one a graduate from the Cairo Medical School and the other a student. Restraint is only rarely employed, and when needed consists of the long-sleeved camisole. There are two or three padded rooms, such as they have in the Bethlem Asylum in Lon-

don, which are occasionally of great service in the treatment of the insane. There is not so much work done by the inmates as might be were there more ambition on the part of the medical direction. All of the wards, beds, and patients' clothing were neat and clean, and the attendants, in their trim uniforms, seemed to be very kind and attentive to their charges. But the nature of the Egyptians is gentle and kindly, and they always treat their unfortunates well. They are only unkind through ignorance.

There is much that is interesting in the forms of insanity met with. One form that I had never seen in my experience in American asylums is that resulting from the use of cannabis indica. Of the two hundred and forty-eight patients sixty men and four or five women were insane from the excessive use of hasheesh. Acute cases which recover and are discharged are almost sure to return. The drug is almost always inhaled by smoking. Hasheesh has been in use in Egypt for over six hundred and fifty years, and although the Government has made strenuous efforts to suppress its importation, it still continues to be smuggled in. There exist in Cairo, unknown to the police, several hasheesh joints. I visited one of these one evening and had no difficulty in purchasing samples of hasheesh for inspection. There were two or three rooms full of men enjoying their pipes and chibouques. The drug is sold in square and diamond-shaped lozenges of a black extract, varying from two cents to ten cents a piece according to quality. The symptoms produced are disorder of the alimentary canal (indigestion and diarrhœa), increased appetite, dilatation of the pupils, drooping eyelids, anæmia, general debility, and delirium. The earliest mental symptom is a marked and increasing timidity, sometimes amounting to a *folie du doute*, or an agoraphobia. Very many cases result in chronic insanity, dementia, or death.

The use of wine and other intoxicating beverages is forbidden by the Koran, and the Egyptians are a very temperate people. Hence insanity from alcoholism is exceedingly uncommon. There were only two or three cases of alcoholic insanity in the asylum at the time of my visit.

Religion is often the cause of insanity, or if not the direct cause, often colors the delusions. One would expect that a religion which so commonly gives rise to extremes of fanaticism, to the orders to be seen in Cairo of Howling and Dancing Dervishes, to the desert pilgrimages to Mecca, to constant poring over the Koran and the like, would have a more than usually bad effect upon the mental balance. It is surely to the influence of the desert that we owe the appearance of so many false prophets. The desert has the peculiarity of developing thoughts in great luxuriance, even if nothing else grows there. If there is anything morbid in one's mind it will grow like an exotic there where there is nothing else to think about. There are a great many false prophets in the Cairo asylum. The Mahdi was another instance. Mahomet was one, and there have been others almost as famous if not as influential. It may be surmised that where polygamy exists as it does in Egypt, and where divorce can be effected at will by the husband, domestic unhappiness should be a frequent cause of insanity among the women.

I was astonished at the number of cases of nymphomania pointed out to me among the Egyptian women in the institution. A singular fact in connection with this is that a form of circumcision (clitoridectomy) is performed on every Egyptian woman as a religious rite during early life. It is not so long ago that some physicians in America advocated clitoridectomy in such cases, and the above may have interest to any such as have a lingering belief in that method of treatment.

It seems that the sexual element is the most prominent of all in the lives of the Egyptians. They are fortunately married in childhood, but that does not prevent great excesses in a natural way among both sexes, nor the commission of nameless crimes among the women in the harems. The sexual element is therefore very prominent in all of the forms of insanity of both men and women. Delusions with a sexual basis are very common.

General paralysis is very rare, and it has yet to be proven that it even exists among Egyptians Dr. Schirs, in nineteen years in Cairo, saw five cases, but none were in Egyptians. Dr. Sandwith, who has practised in Cairo eight years and been a frequent visitor at the asylum, has yet to see a case of general paresis in an Egyptian, and altogether has seen only several in orientals. On the day of my visit to the Cairo institution, four cases were pointed out to me by Dr. Bedr as dementia paralytica, but examination showed that three of them were decidedly not paresis, while the fourth was doubtful. This fourth case presented a few uncertain symptoms of general paralysis and was a Copt. It is rather difficult to explain such a rarity of this disease, while just across the sea, in Greece, it is unusually common. If syphilis and sexual excess were at the root of general paralysis then Egypt would be its Paradise. Dr. Sandwith thinks it may have something to do with the food, for the Egyptians are almost perfect vegetarians.

The Cairo asylum would be a good school for a study of craniometry and racial characteristics. Among the patients I saw there were Egyptians, Copts, Nubians, Soudanese, Abyssinians, Turks, Greeks, Syrians, Circassians, Jews, and Bedouins. A difficulty in the way of cranial measurements would be the scalp disease, from which it would seem that almost no patient is free—favus. And the prevalence of ophthalmic disorders among all classes of people in the country interferes, as I very often found during my sojourn, with diagnosis, not only in some of the nervous disorders but also in the mental cases.

Cairo, March 8, 1892.

A CASE OF PELIOSIS RHEUMATICA.

By GEORGE E. JOSEPHS, M.D.,

PEMBROKE, ONT.

A RATHER unusual case of this disease came under my observation some time ago.

J. L——, male, aged eighteen, single; occupation, baker; habits good; family history good. Previous history: was always rather delicate during his youth, but never had any special sickness; never had rheumatism.

November 5, 1891.– Complained of pains in the wrist and knee-joints, with swelling and tenderness. In addition to these symptoms he suffered from headache, backache, and a sense of chilliness. In a day or so he noticed a bright-red rash coming out on his arms and legs.

November 9th.—I saw the patient for the first time. Temperature, 102.5° F.; pulse, 92, full and regular; tongue slightly coated; both wrists and knee-joints considerably swollen, and very painful and tender. The chest, upper portion of abdomen, and the extensor surfaces of the arms and legs were covered with numerous ecchymotic spots. These were raised, irregular in shape, and varied in color from a bright-red to a reddish-yellow tinge. A few spots were seen on the back, and one or two on the face. No hemorrhages from any of the mucous surfaces. Heart normal and free from any murmurs. Lungs normal. Bowels somewhat constipated. Appetite poor.

November 12th.—Joint symptoms have improved somewhat. Temperature, 101° F.; pulse, 80, full and regular. The ecchymotic spots are fading in color, and the edges are less distinct. The patient is looking much brighter.

November 15th.—A fresh crop of petechiæ is appearing on the thighs and arms. They are much larger than before, and the color of many of them has more of a bluish tinge. The wrists are more swollen and painful. Tongue heavily coated. Temperature, 102° F.; pulse, 85 and regular. Facial expression dull and heavy.

November 16th.—The patient was awakened in the morning by an attack of severe abdominal pain of the nature of colic, with great nausea and vomiting. The

pain was only relieved after giving a hypodermic of morphia. A few hours afterward he passed considerable blood from the bowels.

November 18th.—He was much better to-day. Temperature, 100° F.; pulse, 78 and regular.

November 22d.—Still improving. The eruption has almost disappeared. Temperature, 99° F. Pulse, 70.

November 25th.—A fresh crop of petechiæ is coming out. The wrist-joints are a little swollen and tender. Temperature, 101.5° F.; pulse, 80 and regular. Six or seven hours after the appearance of the fresh eruption very severe abdominal pain came on. It was so severe that he fairly writhed and screamed in agony, and was only relieved after receiving two hypodermics of morphine, one-fourth grain each, the first one failing to have any effect and necessitating a second in forty minutes.

The eruption of petechiæ was very profuse, much more so than before. Some hours after the pain had subsided he passed some blood from the bowels, but not as much as on the former occasion.

November 28th.—Improving. Spots fading. No pain in joints nor any swelling.

December 4th.—Petechiæ nearly all gone. The patient is cheerful, and his appetite is improving. Still he has rather an anæmic appearance. He continued improving till December 12th, when there was a slight recurrence of the eruption on the arms and legs, followed by slight colicky pains. No joint trouble. Temperature, 99° F.; pulse, 72 and regular. From this on he continued to improve. There was an occasional return of the eruption at intervals for three or four weeks longer, but there was no pain nor swelling of the joints. The temperature and pulse remained normal. He was able to resume his occupation as a baker by January 10th, 1892, and is now enjoying excellent health.

Peliosis rheumatica is usually a rather mild disease; more common during early adolescence, and usually running a very irregular course, the prognosis as a rule being favorable. The unusual symptoms in this case were the very severe abdominal pain and the recurrence of fever, and swelling and pain in the joints, with each fresh eruption of petechiæ. Most authors lay but little stress on the occurrence of colic, though the article in Keating's work on "Purpura," states that sometimes abdominal pain and some nausea occur during the course of the disease. In this case the pain on two occasions was very severe. The hemorrhage from the bowels was also a rather unusual symptom. On one occasion the quantity of blood passed was considerable. Fever was also a prominent symptom, the temperature rising 2° F. to 3.5° F. above normal with each recurrence of the eruption. Peliosis rheumatica is, as a rule, an afebrile disease, excepting at the first onset, when there is some elevation of the temperature, but this usually disappears with the appearance of the eruption. In this case there was always more or less fever with each fresh crop of petechiæ, and the temperature declined during the fading of the rash. The joint symptoms were rather more marked than is usual in these cases, and while in the first attack they preceded the appearance of the rash by about forty-eight hours, yet in the subsequent relapses the pain and swelling in the joints appeared almost simultaneously with the reappearance of the petechial spots. The joints usually affected are the knees and ankles. In this case the wrists and knees were affected, there being no pain or swelling in any of the other joints. Although the joint symptoms were so well marked in this case, still I do not think there was anything of a rheumatic element present. Probably the joint trouble was due either to serous effusion into the joint, or else to small hemorrhages into the joint due to congestion of the synovial membranes. I found it difficult to account for the severe colic, but thought it might probably be due to the appearance of a copious eruption of ecchymotic spots in the mucous membranes of the intestines; the hemorrhage from the bowels inclining me to that view. The cause of this trouble is not always plain. The disease often appears in those who are apparently healthy. In this case I attributed it to the occupation of the patient. He worked in a poorly-ventilated shop for a number of hours each day. This, together with poor nourishment, tended to lower his general health, and to interfere with the nutrition of his body.

The treatment in these cases is not very satisfactory. They usually run a long, irregular course, having frequent relapses. Many different drugs have been recommended, such as spirits terebinth., tincture sulph. and sulph. aromat. and tincture iron. None of them seems to have any specific action. General dietetic and hygienic treatment, with treatment of the symptoms as they arise, will probably be as satisfactory as any. In this case I used the spirits terebinth. with mucilage acacia, with very good results, giving iron for the anæmia and morphia to relieve the pain, as well as giving the patient as much nourishment as possible in a concentrated form.

Therapeutic Hints.

Treatment of Cystitis.—Dr. Renaud (*Le Bull. Med.*) has found the following formula very satisfactory in the treatment of cystitis:

℞. Acid oxalic..... gr. xv.
Syr. aurant. cort..... ʒj.
Aq. dest..... ʒiv.

M. S.: To take in dessertspoonful doses in the space of two days.

Treatment of Chronic Prostatitis.—Dr. Oberlaender treats chronic prostatitis with the following suppositories, introduced each night after the bowel has been emptied: ℞. Iodoform, gramme 0.5–1; ol. amygd. dulc., q. s. ut sol.; ol. theobrom, q. s. ut ft. suppos. no. x. The sweet almond oil makes the absorption of the iodoform more certain, and this drug is found superior to iodide of potassium. However, some patients cannot take ten centigrammes daily without showing some signs of intoxication.

Chloralamid.—Dr. Simpson (E. M.) says chloralamid acts more speedily that sulphonal and is not followed by the mental confusion and dulness. Thirty to forty grains is almost certain to be followed by refreshing sleep in nervous insomnia from overwork, worry, and anxiety. In delirium tremens it can be freely used without fear of prejudicial action on the heart. In his experience patients do not become accustomed to it and require increasing doses.

Erythema Nodosum in Children is treated successfully by Dr. Crentz (*Aertzlich. prakt.*, No. 37, 1891) with antipyrin in dose of one decigramme for each year of the child's age, three or four times each day. From eight to fourteen days brought about a cure. In adult cases gramme doses can be given.

Convulsions in Children.—Safe rule in all cases to see that stomach and alimentary canals are emptied. For this, give a full dose of ipecac, repeating in ten minutes if necessary. If this fails to bring on vomiting, tickle the fauces till successful. Give a copious enema, and follow with a half-ounce dose of castor oil. After purging, give chloral till relief is obtained. For a child two years of age, ten grains in a little water can be given per rectum. A child two years of age will stand half the quantity. Morphine may be used if the convulsions are due to uræmia. If scarlet fever or measles is coming on do not purge too freely, as it delays the eruption. The popular hot bath should be used with caution. If the cause of the convulsions is the advent of an infectious disease it may do good, as it brings the blood to the surface of the body and relieves internal congestion. If the convulsions are due to central lesions, when treatment is of no avail the hot bath may possibly be used for the consolation of the parents.—Abstract of talk by Professor J. E. Winters.

Cascara Sagrada as a Tænicide.—Dr. J. C. Stephens, writing in the *Medical Age*, reports two cases in which the use of cascara sagrada was followed by the expulsion of tape worms. In one case acetanilid had been given, but in the other the cascara sagrada alone had been prescribed, so that if the expulsion of the worm was more than a coincidence it must have been due to the action of the sagrada.

Chloride of Iron in Typhoid Fever.—Dr. J. W. Anderson describes in the *British Medical Journal* a mode of treatment for typhoid fever which he has found very effectual. It consists in administering a full dose of the liq. ferri perchloridi fort., namely, 5 minims (for an adult) every hour of the day and night, until a week has elapsed from the complete subsidence of the fever. To enable the patient to take this, the dose is combined with half a drachm of glycerine or 1 drachm of simple syrup, and a few drops of tinct. zingib. fort., and diluted in half a tumblerful of water. If sickness is caused, 5 grains of bismuthi subnit. are given ten minutes before each dose of the medicine until nausea ceases to be produced. In a few days the diarrhœa will be arrested, and thereafter a mild aperient must be given daily as long as the medicine is continued. In a moderately severe case, not brought under this treatment until the end of the first week of fever, it will take, the writer says, ten days to reduce the temperature to normal. If the medicine is not given every hour night and day it will take a little longer; if begun within two or three days of onset of fever, the latter will be gone in about five days.

Biliary Colic.—Dr. J. T. Bagwell has found relief from attacks of hepatic colic by means of resin of guaiac in whiskey (gr. ij.–℥ j.), of which a tablespoonful in water is taken after each meal. It is said also to improve the appetite, increase the secretion of bile, and cure constipation.

Mercurial Inunctions in Diphtheria.—Dr. Moskowitz, of Budapest, reports a number of cases of very severe diphtheria successfully treated by inunctions of mercurial ointment. The ointment is applied twice a day, the neck then being covered with gutta-percha paper and a cloth bandage. No other treatment was employed, except a gargle in a few instances, but every effort was made to keep up the strength by means of nourishing food and stimulants. From two to two and a half ounces of the ointment were consumed during the course of treatment without any signs of mercurialism being noticed.—*Gyógyászat*, No. 52, 2891.

Antiseptics in Cataract Operations.—Graefe uses the following antiseptic precaution in his cararact operations: On the evening before the operation the skin around the eye to be operated on is well washed with ether, and then with a 1 in 5.000 watery solution of sublimate, after which the eye is closed by a pad of boracic cotton wrung out of a sublimate solution, which is removed just before the operation; then the eye is again irrigated with the sublimate solution. The instruments are kept in a four per cent. solution of carbolic acid, but before used are dipped in boiling water. The dressing is kept in a Koch's steam sterilizer, and transferred directly from the latter as soon as required. Despite these elaborate precautions the author states that he has had cases of suppuration in hospital practice occasionally.—*Medical Press.*

Creoline in Eczema.—Dr. Löwengard has found great benefit in eczema from the use of a two per cent. solution of creoline. In one case reported in *Gyógászat*, a complete cure was obtained in three weeks of an obstinate seborrhœa in a six months old child, which had resisted all the ordinary modes of treatment.

For the Itching of Eruptive Fevers.—An ointment, composed of lanoline 50 parts, vaseline 20 parts, and distilled water 25 parts, has been found by Dr. Klein to be a most soothing application for the relief of the itching accompanying the rashes of measles, scarlatina, and chicken-pox.—*The Lancet.*

Benzosol in Pulmonary Tuberculosis.—Walzer proposes this drug as a substitute for creosote or guaiacol in the treatment of phthisis. It is decomposed in the organism into guaiacol and benzoic acid. He gives it in doses of from twelve to twenty-four grains a day divided into capsules of four grains each mixed with chocolate and sugar.

Earache.—Take five parts of camphorated chloral, thirty parts of glycerine, and ten parts of oil of sweet almonds. A piece of cotton is saturated and introduced well into the ear, and it is also rubbed behind the ear. The pain is relieved as if by magic, and if there is inflammation it often subsides quickly.—*Medical Brief.*

For the Dry, Ringing Cough of Influenza the following is a good combination:

℞. Syrupi picis..... ℥ jss.
Spts. ammoniæ arom..... ℥ ss.
Syrupi pruni virg..... ℥ jss.
Potassii iodidi..... ʒ ss.
M. S.: Teaspoonful 2 to 4 hours apart.

—*North Carolina Medical Journal.*

Chronic Rheumatism.—The following has been recommended:

℞. Acidi arseniosi..... gr. j.
Pulv. guaiaci..... ʒ j.
Pulv. capsici..... gr. x.
Pil. aloes et asafœt..... ʒ j.
M. et ft. pil. No. xl. S.: One pill three times a day.

Furuncles.—An ointment of one part red oxide of mercury in one hundred parts of lanolin is said to be very efficacious in aborting furuncles. It should be rubbed in for three or four minutes at a time, once or twice a day. The same application is useful in panaritium.

Glycerine Suppositories.—Dr. Grewcock, writing in the *Medical Recorder*, recommends the use of a little ball of cotton wool the size of a walnut, saturated with glycerine, in place of glycerine injections. When such a ball is inserted into the rectum it soon provokes an abundant evacuation of the bowel.

Borax in Epilepsy.—Dr. Maiset has obtained excellent results in the treatment of epilepsy by borate of soda. He finds it more efficacious than the bromides in symptomatic epilepsy, but less so in the nervous forms.—*Le Progrès Médical.*

Treatment of Hemorrhoids.—Dr. J. Brindley James writes to the *British Medical Journal* of February 20, 1892, that he has for some years been in the habit of treating hemorrhoids by the simple process of applying calomel to them with the finger alone, and without a single exception he has done so with marked success, especially when inflammatory action was obvious in the hemorrhoidal mass, characterized by mucous discharge and hemorrhage, accompanied by most painful sensation of weight in the rectal region. All these symptoms under this simple influence were speedily relieved, with the still more important subsequent advantage of the patient's restoration to ease. "Only a few days ago," he writes, "a patient came to me suffering so acutely that he could neither sit nor walk freely, each movement of the body entailing exquisite pain. I have now seen him thoroughly enabled to pursue his usual occupations in happy immunity from these distressing symptoms."

For Habitual Constipation.—

New York, May 21, 1892.

THE INSENSIBILITY OF WOMEN.

PROFESSOR CÆSAR LOMBROSO contributes to the *Fortnightly Review* an article on the insensibility of women, in which he reaches some rather novel conclusions. Professor Lombroso states that accurate studies as to the relative sensibility of woman as compared with man have never been made. He has himself tested the delicacy of the sense of touch, pain, general sensibility (whatever that may mean), smell, and taste in one hundred women and men. He finds that the tactile sense in men, as measured by the æsthenometer, averages about 1.6 mm., in women of the lower classes it is 2.6, of the higher classes 2 mm. The sense of pain, tested by the electrical algometer, is in young men 64, in older men 78 mm.; in young women 53, and in older women 70 mm. In other words, the sensibility to touch and pain is less in women. Smell and taste are rather keener in women. He does not speak of those most important of all the senses, sight and hearing. Lombroso states that he has been informed by surgeons that women show greater insensibility and less shock from the pain of surgical operations. Their lesser degree of sexual sensibility is generally admitted; their inferior moral sensitiveness is accepted as a fact by Lombroso. It would probably be denied by most women, as well as by many of their chivalrous if not scientific admirers. The supposed lesser sensibility of women is thought to be one reason for their greater longevity.

The data obtained by Lombroso are of value, and will be taken for what they are worth. They are certainly insufficient to prove his case. We fancy that the general experience of physicians is rather against the view which he takes. It is an unquestionable fact that women suffer on the average more pain than men. Neuralgias and headaches are two or three times more common, sensory neuroses predominate in the female sex; motor neuroses in the male. Women bear certain kinds of suffering better than men; they are more patient in invalidism; partly because it brings to them the solicitude and attention which their nature craves. That they feel the pain less, or bear the infliction of pain more stolidly on this account is rather doubtful.

Professor Lombroso has, however, opened up a very interesting field of inquiry, and one which deserves more careful and exact investigation than it has yet received.

COLOR-BLINDNESS AND A PRACTICAL REMEDY FOR IT.

DR. A. E. WRIGHT, discussing the subject of the pathology of color-blindness, adopts provisionally the theory of Hering regarding the perception of color. This assumes that the color-sense can be best accounted for by assuming the existence in the retina of two sensitive layers, each of which is subject to modifications in two opposed directions by a corresponding pair of contrast colors. Hering obtains six fundamental colors: green and red, blue and yellow, white and black, associated together in pairs.

Hering's experiments led him further to conclude that in green-red blindness, which is the common form of achromatopsia, there is either an excessive or insufficient amount of retinal pigmentation.

Apart from any theories, however, Dr. Wright states it to be a fact that total color-blindness is very rare indeed; also that yellow-blue color-blindness is extremely rare. The common form is the green-red blindness. Now, it so happens that in the establishment of signals, green and red lights form the most commonly used colors. Hence from three to five per cent. of men capable of doing work as pilots or engineers, are kept out of such employments, often with results that are almost cruel.

Most color-blind men are not perfectly color-blind, but can readily distinguish yellows and blues. Hence it is proposed that the red lights should have a distinctly yellowish tinge and the green lights a distinctly bluish tinge. In this way the differences between signals could be readily made out by almost all the color-blind.

The suggestion is a good one, for it is impossible always to exclude the color-blind from services calling for a knowledge of color signals. Such a change in the lights would not interfere with the present methods of signalling, and would tend to make it safer.

THE EARL AND THE DOCTORS.

THE Earl of Dunraven, K.P., has undertaken to have what he calls a "Word with the Physicians." The "word" extends over nine columns of *The National Review*, and may therefore be fairly considered a long one. However, the Earl is interesting and discusses a number of practical topics, like influenza, salicin, and the germ theory, in a way that affords entertainment. The earl takes issue first of all with Dr. Maclaggan, because the latter has asserted that salicin keeps off or cures influenza much as quinine does the ague, and also because the doctor says that salicin never causes any unpleasant symptoms. We quite agree with the doctor's critic that both these views are incorrect. But this is only the introduction to a lively attack upon germs, modern views of infection, and modern medical knowledge generally. It is here that his lordship shows ignorance and misconception, regarding what modern pathology and bacteriology have done, which are extraordinary. The time is passed for cheap jests about "germs" and germ "theories." While the subject is not mastered, it has passed the stage of hypothesis and reached that of doctrine. We know with as much certainty as we possess any knowledge, the natural history of many germs and their relation to certain

fevers and infections; every month brings us nearer to that full acquaintance with the nature of disease and its cure and prevention, regarding which the noble earl expresses his doubts, and anent which he exhibits large masses of noble ignorance.

NEAR-SIGHTEDNESS IN MUSICIANS.

In a treatise on the cause of myopia, published some five years ago, Stilling commented on the fact that no author had, up to that time, noticed the frequency of this condition among musicians. "One need but to watch carefully," he said, "any orchestra playing in a theatre or casino, to convince himself of the justice of this observation. I have myself had so much to do with music that I feel competent to pass a tolerable judgment upon the nature of this occupation. I have also had many personal acquaintances among musicians, a very large proportion of whom were near-sighted, the condition being one of acquired occupation myopia." This is due, he believes, to the strain caused by note-reading, especially by the constant looking down. The myopia is, therefore, entirely independent of the kind of instrument played upon. "The drummer and the double-bass singer become just as near-sighted as the pianist or violinist." There is nothing particularly trying in simply reading musical notation, but the strain comes in being obliged always to look downward while the head is carried erect.

Dr. Hermann Cohn has now written an article in the *Berliner klinische Wochenschrift*, of March 21, 1892, with the object of showing that this theory of Stilling's is purely fanciful, being founded upon an erroneous assumption, since the majority of musicians whom he has examined are not myopic. In the first place, he says, the mere fact that many members of an orchestra have glasses does not prove anything, for these may be either convex or concave. Then many musicians have undertaken a long course of theoretical study before beginning to practise on any instrument, and may have weakened the sight through too constant application to books. Finally, many musicians, good as well as bad, do not look at the notes after they have played an air a few times, and so expose the eyes to no special strain. The writer has undertaken to examine the eyes of all the professional musicians in Breslau, and publishes the result of the first series of sixty-two members of the "Orchester-Verein." Of these twenty-five had normal vision, and thirty-seven, or nearly sixty per cent., abnormal vision. Of the latter, three were far-sighted, eight had astigmatism, six had cataract, corneal opacities, etc., and but twenty were myopic. But these were not all myopic as a consequence of their work, for nine were near-sighted when in school; one had been a lawyer's clerk, and had had a great deal of writing to do in a dark room, and was already myopic when he began to play the 'cello; four more had injured their vision by writing music at night for many years. Thus there remained but six out of the sixty-two who could with any show of reason attribute their myopia to the necessity of having to look down when reading their notes.

Professor Steenberg, a well-known alienist in Copenhagen, died of heart disease recently in that city.

News of the Week.

The American Surgical Association will meet in Boston, Mass., Tuesday morning, May 31, and June 1 and 2, 1892, in the Hall of the Natural History Society, on Berkeley Street.

Bellevue Hospital Medical College.—Dr. A. Alexander Smith has been appointed Professor of Principles and Practice of Medicine, and Clinical Medicine, in place of Dr. P. G. Janeway, resigned. Dr. Herman M. Biggs has been appointed Professor of Materia Medica and Therapeutics, Pathological Anatomy, and Clinical Medicine, in place of Dr. Smith, and has been nominated Attending Physician to Bellevue Hospital, in place of Dr. Janeway. Dr. Henry M. Silver has been appointed Demonstrator of Anatomy in place of Dr. Biggs.

Dr. J. M. Keating, of Colorado Springs, has resigned the editorship of the *Climatologist*.

Dr. John William O'Callaghan, a young physician of this city, died on April 29, 1892. He was born at Thompson, Conn., on September 8, 1859. After attending the public schools in Milford, Mass., and Salem, Mass., he entered Harvard College in the fall of 1877, and was graduated with his class in 1881, being admitted to the degree of A.B. *cum laude*. The first year after graduation was given to private tutoring in New Hampshire. At the same time he began studying law, which, however, he soon abandoned. Later he began the study of medicine under practising physicians in New Hampshire and Massachusetts. He entered the second-year class of the Harvard Medical School in 1883, and was graduated in 1885. Dr. O'Callaghan practised in Danvers, Mass., until 1887, when he settled in New York City, opening an office in East Eighty-ninth Street. His health soon began to decline, and he was finally compelled to give up practice and leave the city. The cause of his death was pulmonary phthisis. A solemn high mass for the repose of his soul was sung in the Paulist Church, at Fifty-ninth Street and Ninth Avenue, on May 2d, and the body was taken to Calvary Cemetery for interment. A brother of the deceased, Peter Joseph O'Callaghan (Harvard, '88), a member of the Community of St. Paul the Apostle, was the sub-deacon at the mass of requiem. Dr. O'Callaghan was a man of retiring disposition. He was never married.

Dr. Helen T. Graves, of Kansas City, Mo., died on Sunday evening, April 3d, of pernicious malarial fever. She was a graduate of the Woman's Medical College of Philadelphia, of the Class of '83.

The American Electro-therapeutic Association will hold its second annual meeting in New York, at the Academy of Medicine, on October 4th, 5th, and 6th, under the presidency of Dr. W. J. Morton.

The American Neurological Association will hold its annual meeting in New York, at the Academy of Medicine, on June 22d, 23d, and 24th, under the presidency of Dr. C. L. Dana.

Removal of Clots from Base of Brain—Recovery.—Dr Laplace (Philadelphia) records a case of basal hemorrhage from perforating wound through the left orbit;

coma, convulsions, and signs of compression existed. Trephining was done just above the zygoma, and a specially contrived instrument of malleable wire ("a miniature egg-beater") was insinuated between the dura and the skull to the cavernous sinus, and about a teaspoonful of clot was removed. Consciousness returned four days later, power of speech a week later still, and then recovery was steady and uninterrupted. The patient has anæsthesia of the left eye and internal strabismus.—*Medical and Surgical Reporter.*

Dr. William Cobb Whitfield, of La Grange, N. C., has been elected superintendent of the new Orphan Home, established in Goldsboro by the Odd Fellows of North Carolina.

Registered Midwives for New Jersey.—The following is the law to regulate the practice of midwifery in the State of New Jersey:

1. Be it enacted by the Senate and General Assembly of the State of New Jersey, That every person practising midwifery in any of its branches shall possess a certificate from the State Board of Medical Examiners as hereinafter provided.

2. And be it enacted, That every person now practising midwifery in cities of the first and second classes in this State shall, within thirty days after the passing of this act, personally present to the State Board of Medical Examiners an affidavit setting forth the name, nationality, age, authority, location, and length of practice, together with a certificate of good moral character from some registered physician, resident of the same district; whereupon the Board, on receipt of a fee of one dollar, shall issue a certificate, signed by its president and secretary and bearing the seal of said Board, entitling the person named therein to practise midwifery in this State.

3. And be it enacted, That every person hereafter beginning the practice of midwifery in this State shall appear before the State Board of Medical Examiners and submit to such examinations in midwifery as the Board shall require, and if such examination is satisfactory to the examiners the said Board shall, upon the receipt of a fee of five dollars, issue a certificate the same as provided in section two of this act.

4. And be it enacted, That the person so receiving said certificate shall file the same, or a true copy thereof, with the clerk of the county in which she resides, and said clerk shall file said certificate, or a copy thereof, and enter a memorandum thereof, giving the date of said certificate and the name of the person to whom the same is issued, and the date of said filing, in a book to be provided and kept for that purpose; and for which registry the said county clerk shall be entitled to demand and receive from each person registering the sum of twenty-five cents.

5. And be it enacted, That the State Board of Medical Examiners are hereby authorized and empowered to execute the provisions of this act, and shall hold examinations of candidates for certificates in midwifery at such times and places as may be deemed expedient.

6. And be it enacted, That the State Board of Medical Examiners may refuse licenses to persons guilty of unprofessional or dishonorable conduct, and may revoke licenses for like cause, or for neglect to make proper returns to the various health officers, of births, and the cases of puerperal and other contagious diseases occurring in their practice.

7. And be it enacted, That any person shall be regarded as practising midwifery, within the meaning of this act, who shall publicly profess by advertisement, sign, card, or otherwise to be a midwife, or who shall, for a fee, attend to women in childbirth; but nothing in this act shall be construed to prohibit gratuitous service in case of emergency, nor to the legally qualified physicians or surgeons of this State.

8. And be it enacted, That any person practising midwifery in this State without first complying with the provisions of this act, shall be guilty of a misdemeanor, and shall be punished by a fine of not less than ten dollars nor more than fifty dollars, or by imprisonment in the county jail for not less than ten nor more than thirty days, or both, in the discretion of the court.

9. And be it enacted, That all acts or parts of acts inconsistent herewith be, and the same are hereby repealed, and that this act shall take effect immediately.

Approved, March 28, 1892.

Vienna has a new medical society called the Medical Club.

Death of Dr. Joseph Draper, of Warwick, Mass.—Dr. Joseph Draper was born in Warwick, Mass., February 15, 1834. His early years were spent on a farm, which was very distasteful to him. He commenced the study of his profession with Dr. James Deane, of Greenfield, Mass., afterward attending lectures in New York, and graduating from Jefferson Medical College in 1858. In October, 1859, he was appointed assistant to Dr. Rockwell in the Brattleboro Asylum, and remained until 1865. He was afterward assistant, and some of the time acting superintendent, at the Insane Asylum in Worcester, Mass. In 1870 he was appointed assistant in the New Jersey Insane Asylum, and remained until 1873, when he returned to Brattleboro, and the growth of this institution is attributable to his zeal. In 1881 he was given three months' leave of absence by the trustees to study abroad, and in this time he visited many of the institutions of England and Scotland, and learned much from them for the benefit of the Brattleboro Asylum. He was an active member of the State and County Medical Societies, of the Association of Medical Superintendents of American Institutions for the Insane, President of the Psychological Society, Massachusetts Medical Society, and of the Medico-Legal Society. His contributions to the literature of his profession were very numerous: "Annals of Vermont Asylum for the Insane," covering a period of fifty years of its history; "Sketch of Dr. James Deane," 1858; "Sketch of Dr. W. H. Rockwell," 1858; "Sketch of Dr. C. H. Tenney," 1874; "The Pathology of Insanity," 1875; "The Pathogenesis of Insanity," 1877; "Hysteria in Insanity," 1879; "Neurasthenia of the Ganglionic Nervous Centres," 1881; "Insanity in Great Britain and the Continent of Europe," 1882; "The Responsibility of the Insane Outside of Asylums," 1883; "Vermont Asylum in the History of Brattleboro," 1880; "Insanity in Vermont, 1835-85," 1885; "Obituary of Dr. Sumner Putnam," 1888; "The Oath of Hippocrates," 1889; "Nervous Exhaustion," 1890; "Subjective

Delusions," 1890. He was a prominent member of the Professional Club at Brattleboro, and has lectured before them, and in other towns. Dr. Draper was married at Warwick, Mass., to M. J. Putnam, in January, 1863, who still survives him.

American Pediatric Association.—Officers elected for the ensuing year: *President*, Dr. Blockader, of Montreal; *1st Vice President*, Dr. Keating; *2d Vice-President*, Dr. Earle, of Chicago; *Secretary*, Dr. Samuel Adams, of Washington; *Treasurer*, Dr. Townsend, of Boston; *Recorder*, Dr. Watson, of Jersey; *New Member of Council*, Dr. Rotch, of Boston. New members elected were: Dr. J. P. Crozer Griffith, of Philadelphia, and Dr. T. F. Sherman, of Boston.

Dr. Kitasoto, the eminent Japanese bacteriologist, was recently in this city on his way home to Tokio. The Prussian Minister of Public Instruction recently conferred upon him the title of Honorary Professor.

The Ohio State Medical Society held its forty-ninth annual session in Cincinnati, May 4th, 5th, and 6th. It was largely attended, and was a very pleasant meeting. The Cincinnati Medical Societies gave a reception and banquet at the Burnet House to the visiting physicians and ladies, on Thursday evening. Put-In-Bay was selected as the place of the next meeting, in June, 1893. The officers elected for the coming year are: *President*, Dr. Dudley P. Allen, of Cleveland; *Vice-Presidents*, Dr. N. P. Dandridge, of Cincinnati; Dr. E. C. Brush, of Zanesville; Dr. C. A. Kirtley, of Toledo; Dr. W. A. Dixon, of Ripley; *Secretary*, Dr. T. A. Fitzpatrick, of Cincinnati; *Assistant Secretary*, Dr. J. A. Spence, of Crestline; *Treasurer*, Dr. G. I. Cullen, of Cincinnati; *New Member of Finance Committee*, Dr. P. P. Pommerine, of Berlin; *Committee on Ethics*, Dr. C. S. Van Pelt, of Toledo; *Publication*, Dr. L. S. Colter, of Cincinnati; *Legislation*, Dr. C. E. Beardsville, of Ottawa; *Admission*, Dr. A. R. Baker, of Cleveland. Clinics were held at the various hospitals, and a number of operations performed in honor of the visitors. Aside from the regular programme, the constitution was changed to conform with that of the American Medical Association, and the session of 1892 adjourned.

The Kentucky State Medical Society met at Louisville, Ky., May 4, 5, and 6, 1892. Dr. H. Brown, of Hustonville, presided and gave his address on "The Use and Abuse of Medicines." This was followed by a humorous address from Rev. C. J. K. Jones, of Louisville, on "My Doctor." This was greeted by round after round of applause, and a vote of thanks was unanimously tendered the reverend gentleman for the hit of the evening. Officers elected for the coming year are as follows: *President*, Dr. Arch Dixon, of Henderson; *1st Vice-President*, Dr. T. B. Greeley, of Orel; *2d Vice-President*, Dr. Turner Anderson, of Louisville; *Treasurer*, Dr. J. B. Kinnaird, of Lancaster; *Secretary*, Dr. Steele Bailey, of Stanford; *Board of Censors*, Drs. B. V. Stone, of Hopkinsville; W. L. Bodman, of Louisville; Jesse Smith, of Hodgenville. Interesting reports and papers were read by Dr. W. B. McClure, of Lexington, on "Otology;" Dr. William Wathen, on "Pelvic and Abdominal Surgery;" Dr. J. W. Irwin, of Louisville, on "Some Sequelæ of Influenza; Dr. J. H. Letcher, of Henderson, on "Intestinal Anastomosis; Dr. William Cheatham, of Louisville, on "The Recent Treatment of Granular Lids;" Dr. J. B. Marvin, of Louisville, on "Some Diseases of the Spinal Cord;" Dr W. R. Blue, of Louisville, on "Electric Illumination of the Bladder;" Dr. Fayette Dunlap, of Danville, on "The Present Status of Brain Surgery;" Dr. G. Frank Lydston, of Chicago, on "A Case of Syphilitic Circinnate;" and a number of other instructive and carefully prepared papers were read. The resident physicians royally entertained the visiting members and ladies at a reception and banquet at the Galt House, at which fully five hundred were present. A number of private dinners and entertainments were given. Dr. Simon Flexner, of Louisville, won the Marvin prize of $50. Subject of Essay, "Etiology of Croupous Pneumonia." The Society closed its pleasant and profitable thirty-ninth annual session, to meet next year at Frankfort.

Memorial Pavilion to Dr. Dubois.—At a meeting of the Trustees of the New York Eye and Ear Infirmary, a few days ago, the family of the late Dr. Abram Dubois, for nearly half a century the operating surgeon of the infirmary, proposed to erect a pavilion in his memory, to cost about $80,000. The Trustees gladly accepted the offer. The memorial will be a monument to a man of self-sacrifice, who devoted himself to the relief of human suffering. The New York Eye and Ear Infirmary, which was established in 1820 by Dr. Edward Delafield and Dr. J. Kearney Rogers, is one of the oldest in this country.

Programme of the Seventh Annual Meeting of the Association of American Physicians, to be held in Washington, May 24th, 25th, and 26th: "President's Address," by Henry M. Lyman, of Chicago, Ill.; General Business; "The Cold-water Treatment of Typhoid Fever," by G. Wilkins, of Montreal; "The Treatment of Follicular Tonsillitis," by G. M. Garland, of Boston; "A Collective Investigation in Regard to the Value of Quinine in Malarial Hæmaturia or Malarial Hæmoglobinuria," by H. A. Hare, of Philadelphia; "Alcoholism," by T. S. Latimer, of Baltimore; "Practical Results of Bacteriological Researches," by G. M. Sternberg, U. S. N.; "The Treatment of Experimental Tuberculosis by Koch's Tuberculin, Hunter's Modifications, and other Products of the Tubercle Bacilli," by E. L. Trudeau, of Saranac Lake; "Report of a Case of Glanders, with Results of Bacteriological Study," by William Pepper, of Philadelphia; "The Bacteriological Study of Drinking-water," by V. C. Vaughn, of Ann Arbor; "The Morbid Anatomy of Leprosy," by Heneage Gibbes, of Ann Arbor, Mich.; "Discussion on Dysentery—Etiology and Pathology," by *Referee* W. T. Councilman, of Baltimore; "Symptomatology, Complications, and Treatment," by *Co-Referee* A. B. Ball, of New York; "Treatment of Acute Dysentery by Antiseptic Colon and Rectal Irrigation," by W. W. Johnston, of Washington; "A Contribution to the Study of Hepatic Abscess," by W. C. Dabney, of Virginia; "Pulsating Pleural Effusions," by James C. Wilson, of Philadelphia; "A Case Presenting the Symptoms of Landry's Paralysis, with Recovery," by F. T. Miles, of Baltimore; "A Case Showing Symptoms of Landry's Paralysis—Recovery," by A. McPhedran, of Toronto, Canada; "The Areas of Anæsthesia in Spinal Cord

Lesions as a Guide to Localization," by M. A. Starr, of New York; "A Study of the Seasonal Relations of Chorea and Rheumatism for a Period of Fifteen Years," by Morris J. Lewis, of Philadelphia; "The Significance of Intermission in Functional Nervous Diseases," by W. H. Thomson, of New York; "Misconceptions and Misnomers Revealed by Modern Gastric Research," by Charles G. Stockton, of Buffalo; "The Production of Tubular Breathing in Consolidation and other Conditions of the Lungs," by Charles Cary, of Buffalo; "The Different Forms of Cardiac Pain," by Samuel G. Chew, of Baltimore; "The Late Systolic Murmur," by J. P. Crozer Griffith, of Philadelphia; "Tube Casts and their Diagnostic Value," by I. N. Danforth, of Chicago; "Studies in Hypnotism," by B. F. Westbrook, of Brooklyn; "Influenza, and Some of its Present Aspects," by Morris Longstreth, of Philadelphia.

Regulation of Dispensary Practice.—The Ophthalmic Hospital of Cincinnati issues and uses the following slips:

Ophthalmic Hospital and Dispensary, Cincinnati, O.

It has been suggested that you are not a proper subject for treatment in this hospital. This institution is for those in poverty and distress *only*, and it will be necessary for you to furnish evidence on this blank from some responsible party that you are a proper person for the recipiency of its charity.

(Signed) ——— ——,
Executive Officer, Ophthalmic Hospital.

Date, ———, 189—.

——— —— is known to me to be worthy of the charity offered by the above institution.

(Signed) ——— ——.

It seems to us that this is a long step in advance, and one that might be adopted by all the dispensaries without detriment to their attendance, but with decided benefit to the medical profession in general.—*Lancet-Clinic.*

The Question whether a Negro Physician shall be received at the post-graduate institutions of this city is agitating the managers.

The World's Fair Entertainment Committee of the Medical Profession of Chicago recently met and organized. The committee has undertaken preparations for extending hospitality to members of the profession visiting the World's Fair, by means of medical head-quarters, and in exceptional cases by the giving of banquets and receptions. The following reported themselves as permanently authorized to act for their respective societies: Dr. John E. Owens, Dr. A. E. Hoadley, and Dr. J. B. Murphy, representing the Chicago Medical Society; Dr. Harold N. Moyer, Dr. D. R. Brower, and Dr. C. W. Earle, representing the Practitioners' Club; Dr. William E. Clark, Dr. C. D. Wescott, and Dr. A. H. Foster, the Pathological Society; Dr. J. H. Etheridge, Dr. F. E. Waxham, and Dr. L. L. McArthur, the Gynecological Society; Dr. T. T. Nelson, and Dr. Archibald Church, the Medico-Legal Society; Dr. J. C. Cook, Dr. H. H. Deming, and Dr. Milton F. Coe, the South Side Medical Society; and Drs. Hektoen, Winthrow, and Holmboe, the Scandinavian Medical Society.

Hot Springs has a medical journal. It is conducted by Drs. Keller, Franklin, Holland, and Minor.

Reviews and Notices of Books.

ESSENTIALS OF MEDICAL ELECTRICITY. By D. D. STEWART, M.D., Demonstrator of Diseases of the Nervous System, and Chief of the Neurological Clinic in the Jefferson Medical College, etc., and E. S. LAWRANCE, M.D., Chief of the Electrical Clinic, and Assistant Demonstrator of Diseases of the Nervous System in the Jefferson Medical College, etc. With Sixty-five Illustrations. Philadelphia: W. B. Saunders. 1892.

THIS is No. 23 of Saunders's "Question Compends." The subject of medical electricity, so puzzling to many practitioners, is here presented in a lucid and pleasing manner, yet briefly. The authors' experience as teachers is here put to good account, as it has shown them what points are most apt to be misapprehended by the student, and led them to particular pains in making these clear. The book ought to serve as a useful introduction to Beard & Rockwell's or other elaborate treatises on this important branch of medicine.

A TREATISE ON BRIGHT'S DISEASE OF THE KIDNEYS; its Pathology, Diagnosis, and Treatment, with Chapters on the Anatomy of the Kidney, Albuminuria, and the Urinary Secretion. By HENRY B. MILLARD, M.A., M.D., Fellow of the Academy of Medicine of New York, and of the American Academy of Medicine; Foreign Corresponding Member of the Academy of Medicine of Paris, of the Verein Deutscher Aerzte of Prague, of the Société d'Hydrologie Médicale of Paris, of the Royal Academy of Medicine of Rome; Honorary Member of the Société Anatomique of Paris, etc. Third Edition, revised and enlarged. 8vo, pp. 322. New York: William Wood & Co. 1892.

THE second edition of this work was exhausted more than two and a half years ago, and the third is a welcome addition to the literature of the subject of which it treats. Extensive changes and additions are manifest. The chapter on tests for albumin has been entirely rewritten, and is important as showing the real value of the numerous tests in use, and the liability to mistake mucin and various protein substances for serum albumin. The chapter on physiological or normal albuminuria, so called, has also been rewritten, the author no longer believing that this exists, and now rejects *in toto*, as unsatisfactory, the hurried experiments of Chateaubourg and Capitan, published in 1883, and shows that numerous cases reported as such are only mucinuria. This chapter is of interest, as bearing upon the relations of albuminuria to life insurance, and assigning to it its true significance as to harmlessness or importance.

In showing how mucin often produces the reaction of albumin, the author writes as follows: "It is extremely difficult sometimes to differentiate mucin from serum albumin. I have made a large number of experiments which show that any liquid containing secretions from irritated or inflamed mucous surfaces will give a distinct reaction with nitric, picric acid, Tanret's, and my own test (both these latter containing acetic acid), and especially with citric acid, which is the most sensitive test for mucin. Secretions from the bronchial, pharyngeal, or nasal mucous membrane, not purulent, but as they may occur in any ordinary cold, macerated, heated, not to the boiling-point, and filtered, will give a reaction with all the above tests. I have mixed these, after filtering, with non albuminous urine with the same results. And this is not surprising, inasmuch as mucus usually contains in solution organic nitrogenous substances (as well as salts), mucosine, and cells of the mucous membrane from which the mucus is derived. It is in some respects really albuminous. And it is this element, I believe, which in many cases constitutes the so-called 'physiological albuminuria.'"

Much new matter has been added, especially upon the ocular derangements and mental disturbances of Bright's

disease, the bacterial origin of nephritis, the albuminuria of pregnancy, the danger of anæsthetics in nephritis, the etiology of nephritis, and upon the treatment. The author does not believe in the albuminuria of pregnancy, that is, an albuminuria directly caused by it, but that the albuminuria in pregnancy in many cases, with sufficient care and sensitive tests, would be found to have pre-existed or that it was contracted during pregnancy, and cites several cases to show this. The chapter on the mental derangements of Bright's disease is of importance from a medico legal point of view. The use and justification of the employment of the various anæsthetics in albuminuria is fully discussed. As regards treatment, nearly all known remedial measures of value are referred to. The mechanical execution of the book is excellent and even elegant.

A History of Epidemics in Britain, from A.D. 664 to the Extinction of the Plague. By Charles Creighton, M.A., M.D., formerly Demonstrator of Anatomy in the University of Cambridge. Cambridge: At the University Press. 1891.

This scholarly work is unique, and fills a hitherto unoccupied niche in English history, bringing together as it does, in one connected narrative, materials bearing on the origin, progress, and sequels of the great waves of sickness and death which have swept from time to time over the British Isles. After a general review of the earliest epidemics, and of leprosy in the middle ages, the author gives us histories of the black death of 1348–49, the sweating sickness of 1485–1551, the plague, jail fevers, influenzas, and other fevers of the Tudor period; the French pox, small-pox, and measles; plagues, fevers, and influenza from the accession of James I. to the Restoration; sickness among the sailors and colonists in Drake's expeditions, in Jamaica, Virginia, and elsewhere, and finally, of the great plague of London, in 1665–66. The book is one of absorbing interest as well as being a most valuable addition to historical literature, and Dr. Creighton has done a work which should and will win for him the lasting gratitude of all scholars.

Surgical Diseases of the Ovaries and Fallopian Tubes, Including Tubal Pregnancy. By J. Bland Sutton, F.R.C.S., Assistant Surgeon to the Middlesex Hospital; late Hunterian Professor, and Erasmus Wilson Lecturer, Royal College of Surgeons, England. With 119 Engravings and 5 Colored Plates. Pp. xvi., 500. Philadelphia, Pa.: Lea Brothers & Co. 1892.

To gynecologists the name of Mr. Sutton has long been familiar as that of a conscientious worker in pelvic pathology, as well as a comparative anatomist of wide reputation. The present volume contains the substance of valuable papers which have been scattered throughout journals and society reports during the past five or six years, and deserves the careful attention of general readers as well as of specialists. While every chapter includes something that is fresh and interesting, the portions devoted to diseases of the Fallopian tubes and to extra-uterine pregnancy are especially instructive, bearing as they do intrinsic evidences of careful observation and minute personal study. The literature of ovarian and tubal disease is so overburdened with useless "library papers" (as Tait has called them) that we welcome as a refreshing innovation a monograph which is avowedly based upon incontrovertible facts. It cannot be denied that the work has been unduly expanded by the introduction of many chapters on diagnosis and surgical treatment, which appear to serve as a sort of padding and divert the reader's attention from the real gist of the matter—the pathological anatomy of the adnexa. Nevertheless, everything that the writer has to say is stated in such a clear, practical way that one is disposed to excuse this weak side in an otherwise able work.

The author's style is singularly concise—almost epigrammatic. Statements which in a less weighty authority might appear too dogmatic gather force by the positive manner in which they are made. The illustrations, which are nearly all new, are unusually good, and the entire volume is an admirable specimen of the bookmaker's art.

From the introductory sentences of the preface one would infer that the author held the literary honesty of the gynecologists in light esteem; possibly his criticism extends only to American specialists, who certainly have displayed "a notorious amount of egoism." Uneven as the work is, its merits so far exceed its faults that we have no hesitation in pronouncing it the best monograph of the kind which has yet appeared.

Diagnostik und Therapie der Magenkrankheiten. Nach dem heutigen Stande der Wissenschaft bearbeitet von Dr. I. Boas, Specialarzt für Magen- und Darmkrankheiten in Berlin. I. Theil. Zweite neu bearbeitete Auflage. Leipzig: Verlag von Georg Thieme. 1891.

The value of this work on the "Diagnosis and Treatment of Diseases of the Stomach," at least its appreciation by the profession in Germany, is shown by the fact that a second edition was called for in less than one year after the appearance of the first. In preparing this the author has taken note of all the most recent advances in the physical examination of the stomach, and the latest discoveries in the chemistry of digestion. This first volume deals with the general diagnosis and treatment of gastric diseases, and contains chapters on the anatomy and physiology of the stomach, general methods of examination by physical and chemical means, and treatment, general and local, mechanical and medicinal. The text is illustrated with twenty-eight wood-cuts.

Diseases of Urinary Apparatus, Phlegmasic Affections. By John W. S. Gouley, M.D., Surgeon to Bellevue Hospital. Pp. 342. New York: D. Appleton & Co. 1892.

In this his latest work Dr. Gouley has given to the profession almost a classic, certainly an authority, on the subject. He is noted the world over for the depth of his knowledge, the extent of his researches, and for the purity and beauty of his diction. The work in hand is a fine example of each. No more scientific work, or nore more valuable, either in technical or practical knowledge, has ever been published on the subject—a subject, by the way, in which Dr. Gouley stands among the foremost of the world's physicians and authors. He begins by saying that a correct conception of disease cannot be formed without previous study of the nature and uses of the organs of the human body, disease being a departure from the normal state of any of these organs. Consequently his opening chapters are devoted to the anatomy and physiology of the genito-urinary tract. They are not claimed to be exhaustive, and yet they contain the essentials with much that is of value to the surgeon especially, that can be found in no anatomy or physiology. Being a brilliant and thorough surgeon himself, the author knows full well the anatomical needs of the operator. Before special subjects are taken up there are chapters on the general pathology of the urinary apparatus. Here is a mine of information. It is a foundation upon which extended knowledge can be easily built. Disease follows simple laws, which, once understood, make the whole subject easily acquired and comprehensible. Dr. Gouley's exposition of the laws are admirable. It is here he explains his term phlegmasic affections—the subject of his work. The term "is intended to convey the idea of a morbid process, one of the local nutritional changes which, when visible and tangible, is ordinarily characterized by heat, redness, swelling, and pain, and which is now believed by many pathologists to be generally caused by microbic invasion." Other infections in his classification are stenotic, auxetic, neoplasmatic, cystic, toxic, traumatic, etc. Phlegmasic affections include interstitial nephritis, pyelonephritis, perinephritis, cystitis, prostatitis, and urethritis. Each of

the subjects is exhaustively considered in the author's masterly way, special attention being paid to treatment. All in all, the work is a most valuable one.

Précis d'Assistance aux Opérations. Préparation du Malade et des Instruments, Anesthésie, Soins Consécutifs. Par le Dr. Paul Thiéry, Ancien Interne des Hôpitaux, Prosecteur et Lauréat de la Faculté de Médecine de Paris, Membre de la Société Anatomique. Paris: A. Maloine. 1892.

This is a little work that ought to be of the greatest assistance to the young hospital interne in familiarizing him theoretically with what he will have to learn practically later in his term of service. But it would perhaps be even more useful to the general practitioner whose knowledge of operative surgery is rusty, but who is required to assist the surgeon whom he has called in to operate upon one of his patients. Under each operation the author gives in a few words what it is necessary to do in the way of preparation of the patient, then gives lists of the instruments, sutures, drainage material, dressings, etc., that will probably be needed, and finally formulates directions for the after-treatment of the patient.

The Year-book of Treatment for 1892. A Critical Review for Practitioners of Medicine and Surgery. Pp. 491, 8vo, cloth. Philadelphia: Lea Brothers & Co. 1892.

The "Year-book" is too well known and too highly appreciated to need comment. The immense strides taken in the progress of medicine in all its branches make it impossible for any one to keep up with the times. Hence the necessity of the book in hand. Its score of co-authors sift out what is useful in literature and presents it in a concise, readable form. Thus, with comparatively little labor, the busy practitioner gets the gist of medical literature the world over. Every branch of medicine is covered—new remedies, old ones with new applications, new operations, all receiving attention.

A Manual of Operative Surgery. By Frederick Treves, F.R C.S., Surgeon to and Lecturer on Anatomy at the London Hospital; Member of the Board of Examiners of the Royal College of Surgeons. With 422 Illustrations. Philadelphia: Lea Brothers & Co. 1892.

Mr. Treves has rendered a service to his fellow-surgeons, and especially to the younger generation just stepping upon the scene, in giving them such a useful guide to their art. The work is contained in two large octavo volumes, of 775 pages each. The first volume is devoted to a consideration of the general principles of surgery, anæsthetics, operations upon arteries and nerves, amputations, excisions, and operations upon bones, joints, and tendons. In the second volume the author treats of plastic surgery, operations upon the neck and abdomen, operations on hernia, operations upon the bladder, scrotum, penis, and rectum, and upon the head and spine, thorax and breast.

The most noticeable defect in the work as a whole is a certain want of uniformity in the treatment of the different subjects as regards their relative importance, some important parts being rather cursorily treated while others of comparative insignificance are gone into in a most thorough manner. It seems to us, too, that the author is a little sweeping in his denunciation of the director, for there are some cases in which it is most useful. He means, of course, that the surgeon should be bold and of steady hand, and ought to rely first of all upon his anatomical knowledge and manual dexterity, and the more the surgeon comes up to that standard the less reliance does he place upon the director. But every surgeon is not up to that ideal, and he had far better rely upon his director than work irreparable injury to his patient. We are rather sorry, finally, to see Mickulicz's or Wladimiroff's osteoplastic resection of the foot receive an entire chapter to itself, for it is time it was consigned to the limbo of impracticable and useless operations. Mr. Treves, it is true, does not endorse it, and states that it is still on trial and has been subjected to much adverse criticism; still, we believe it is altogether undeserving of even such notice as it has.

But these are all minor points that do not seriously detract from the value of the book. The author's directions for operation are most excellent and deserve to become classical, the style is good, the cuts are much above the ordinary, and the typography is of the sort that delights the weary eye.

A Text-book of Nursing, for the Use of Training-schools, Families, and Private Students. Compiled by Clara S. Weeks-Shaw. Second Edition, revised and enlarged, with Illustrations. Pp. 391. New York: D. Appleton & Co. 1892.

The best evidence of the intrinsic excellence of this well-known work is afforded by the fact that during the seven years which have elapsed since its first publication it has steadily held its own as the favorite text-book in the majority of the principal training-schools in this country, in spite of the fact that many rivals have appeared in the interval. Its essential features are clearness, common-sense, and entire absence of pedantry. We are not exaggerating when we say that the laity are under great obligations to the authoress for instructing them in the principles of caring for the sick. The book is written in such a way that "he who runs may read," and every page bears the impress of personal experience. The present edition shows internal evidence of conscientious revision. Former useless matter has been omitted, and the attempt to keep the work abreast of modern advanced surgery has been highly successful. Any nurse who makes it her constant companion, and who becomes thoroughly imbued with the spirit of the introductory chapter, can hardly fail to become what a true nurse should be—indispensable to the physician. Good nurses are, unfortunately, not so common as one would infer from the number of excellent training-schools in New York alone. The affection known as "big head" plays sad havoc with recent graduates, both male and female. While it is true that a perfect nurse is born, not made, self-discipline, an earnest purpose to attend strictly to her own business and not to interfere with the doctor's, will make any young woman of average intelligence successful in her profession.

The improvements in the revised edition are indicated in the preface. They appear mainly in the chapters on operations. The necessary preparations for aseptic laparotomy are clearly described, and we note with approval a new chapter on gynecology. Aseptic midwifery also receives due attention. The excellent work of the well-known firm whose names appear on the title-page is seen in this as in all their books.

Human Monstrosities. By Barton Cooke Hirst, M.D., Professor of Obstetrics in the University of Pennsylvania, and George A. Piersol, M.D., Professor of Histology and Embryology in the University of Pennsylvania, Philadelphia. Large folio, 13 × 17 inches. In Four Parts, to contain about 150 pages of text, with 39 full-page Photographic Plates from Nature, and many Engravings. Part II., pp. v., 89–112; Plates viii.–xx. Philadelphia: Lea Brothers & Co. 1892.

We have already referred at length to the salient points of this beautiful work, the second volume of which, containing the description of monstrosities, is even more attractive than the first. There are more plates and less space devoted to the text. The conditions known as anencephalus and exencephalus receive the principal attention. We can only repeat that the work is one which reflects great credit upon American obstetric literature, and deserves a place in the library of every specialist as well as student of anatomy.

Society Reports.

MEDICAL AND CHIRURGICAL STATE FACULTY OF MARYLAND.

Ninety-fourth Annual Session, held at the Hall of the Faculty, Baltimore, April 26, 27, 28, and 29, 1892.

WILLIAM H. WELCH, M.D., PRESIDENT, IN THE CHAIR.

DRS. G. L. TANEYHILL, R. T. WILSON, AND WILLIAM B. CANFIELD, SECRETARIES.

Acute Lobar Pneumonia in the Light of Bacteriological Investigation was the subject of the President's Address. The organism which is now generally conceded to be the cause of acute lobar pneumonia has had a variety of names, but the best is, in my opinion, the diplococcus pneumoniæ. It was discovered in September, 1880, by Sternberg, in his saliva, and was next described in December of the same year by Pasteur, who came on it in inoculating a rabbit with the saliva of a child dead with hydrophobia. In 1885 Sternberg showed the identity of the saliva organism and the diplococcus pneumoniæ, and in July, 1887, A. Fraenkel investigated the same organism. At this time there was confusion between the diplococcus pneumoniæ and the pneumococcus of Friedlander. This latter is a bacillus, the pneumo-bacillus of Friedlander; it is a totally different species, and probably has nothing to do with the causation of acute lobar pneumonia. Since this time the literature of the subject has increased wonderfully, and I shall not weary you by attempting to trace the subject from its beginning to the present time.

The pneumococcus is an organism, lancet-shaped or oval, with one end more pointed than the other, and it is called diplococcus lanceolatus from this shape. The shape is very variable: while the oval is the most common, it is not characteristic, and it is often spherical. It is usually found in pairs, two together, hence the name diplococcus. It may also occur in short chains, and occasionally in long chains. These long chains may be indistinguishable morphologically from the streptococcus, and may be even in colonies indistinguishable, by our present known methods of culture, from the streptococcus. If the pneumococcus can occur under certain conditions in the form of chains, how can we decide whether it is the pneumococcus or a form of the streptococcus? This is the interesting point at present. This difficulty we are not likely to encounter in acute lobar pneumonia.

A characteristic point of difference is the presence of a capsule around the pneumonia organism. These capsules are sometimes easily demonstrable, and sometimes not. The capsules were for a long time not easy to stain, but I have at last come upon a method which yields absolutely positive results in my hands. The presence of the capsule pertains to the organism only in relation to the tissues and organs of the body, and the capsule is not demonstrable in organisms from cultures. The organism dies in large numbers in the body. In the exudate of pneumonia it is astonishing to find how many of these organisms are present. The three distinguishable points of the pneumococcus are expressed in the name, pneumococcus diplococcus lanceolatus capsulatus In cultures the pneumococcus grows best at a temperature approaching the body temperature. For this reason gelatine is not so good a medium, as it melts at a low temperature, and this is one reason why Friedlander failed to find the organism, because he used gelatine. In cultures they will not grow usually at a temperature below 65° F., but when they have been transplanted they will grow at lower temperatures. They grow on almost all our nutrient media, nevertheless there is no other known organism that possesses such a wide range of growth, that is so particular as to the exact composition of the medium on which it grows as the pneumococcus. The medium should always be carefully tested before, for a very little thing wrong in the composition of the nutrient medium will lead to a failure in the culture of the organism. The properties of the medium which are best adapted for the growth of the organism are, first, its reaction. It should be slightly alkaline and should be made up of the right sort of peptones. Merck's peptones are the best. These two points can be watched with considerable regularity, but the difference which the different kinds of beef make is very hard to understand.

It is not necessary to describe the growth of the organism. It grows best at a high temperature, and in an incubator at body temperature. It does not liquefy gelatine, and grows preferably in agar-agar. Its growth in agar-agar is not easy to see. It coagulates milk, and grows as well with as without oxygen. As a rule, the more virulent the organism the more difficult to cultivate. A very important characteristic is its short vitality. No other organism dies so easily. It dies in less than a week, and has died three days after it was planted, and after two weeks it is non-virulent. The best culture medium is a mixture of agar-agar and gelatine. It is impossible to keep the virulence of the organism for any length of time. The disease-producing or pathogenic power of the organism is very short and generally variable, and some have no virulence. Some kill rabbits within twenty-four hours. The pathological effects of the organism depend on four factors: 1, The animal itself; 2, the degree of virulence of the organism; 3, the number of bacteria which get into the body; 4, the size of the inoculation.

The animals which are most susceptible are rabbits and mice. Mice are more apt to die with material containing the pneumococcus than rabbits, the latter not infrequently surviving the inoculation. Guinea-pigs are relatively insusceptible. There is a difference in different species and in animals of the same species. The number of bacteria inoculated makes a difference, and from this there is a variability in the pathogenic effects. This is not so true with the virulent bacteria as with the less virulent. We can produce different effects on animals by the size of the dose. The site of the inoculation is also very important. The animals usually die sooner when the organisms are injected directly into the blood and peritoneum, and they live longer when the organisms are injected subcutaneously.

The symptoms are fever, diarrhœa, and albuminuria. The elevation of temperature is almost constant. The organisms invade the blood shortly before death, and it is the poisonous products of the organisms in the blood that cause death. The urine of rabbits is normally albuminous, but the albumin is slight in amount. In this case the albumin is very abundant. There is acute pulmonary œdema which may also cause death. In the type more characteristic of the more acute symptoms the animal dies within forty-eight hours, the spleen is enlarged, there are necrotic foci in the liver. It is interesting to note that these necrotic foci have also been found in the liver of human beings who have died of pneumonia. There is an alteration in the kidneys in the majority of cases, and a filling up of the renal glomeruli with fibrin, making a sort of fibrin thrombosis. This has also been demonstrated in human beings. The heart is nearly always fatty and the lungs œdematous.

A second type of the disease is when the animal lives for five or ten days, and when there is a very extensive fibro-purulent exudate along the subcutaneous walls. In this case no organisms can be found in the body, and the exudation along the abdominal walls, where the inoculation was done, prevents the organism from getting into the body—evidently a case where nature throws out a protective wall to keep the invading organisms out. In this case there is a tendency to inflammation of the serous membranes. There is little septicæmia, and while the pneumococcus is in the subcutaneous tissues there is no organism in the body or blood.

In a third type of the disease there is a formation of

localized abscesses. The diplococcus pneumoniæ is a more or less pyogenic organism. These abscesses may be large or small, but they do not generally cause the death of the animal.

A final form of the disease is that in which the animal has died not from infection, but from intoxication. In one case an inoculated rabbit died in two days, and a second rabbit, inoculated from the first, died in sixteen days. In the first animal the organisms were found in abundance, but in the second animal only empty capsules of the organism were found. This rabbit had died from intoxication—was killed by a poison left by the organisms, which had all disappeared. This poison is called pneumotoxine, and is a chemical poison produced from the pneumococcus. It is not a ptomaïne; it is not a crystallizable alkaloidal substance, but it is albuminous and proteid. It has never been isolated in a pure state. The power of these poisons is very great, and the local action is due to them. That is probably the cause of the filling up of the lungs with exudate.

We can render animals immune. Inoculation with a small quantity of a virulent culture, with a larger quantity of a weaker culture, or with the substance itself, will protect the animals for a time or make them immune. The protection of the animals is due to the formation of a special substance which is undoubtedly in the blood. It is called the immunity-producing substance.

The diplococcus pneumoniæ is the only organism which is constantly present in this disease. We can reproduce the disease in animals. It is sufficient to cause an exudate in the body. This new substance is in the blood at or after the crisis, and was not there before the crisis. This has been proved in human beings. Is it the sole cause of pneumonia? This is *sub judice*. In my mind I think it is the only cause. It is unreasonable to think that a disease which runs a course so universally the same can have several causes. There are two arguments against the diplococcus. One is the finding of other organisms in the disease, and the other is the failure to find the diplococcus. Other organisms do get in the lung, but that is natural.

It is not easy to find the organism. We may use several ways: 1. Examine cover slips. 2. Always inoculate two animals, a rabbit and a mouse. 3. Make cultures. Many have relied on only one of these procedures. Negative cases may occur. The origin of the disease is hard to name. There may be two modes of infection. The organism is widely distributed. It is frequently found in the mouth of healthy individuals (about twenty per cent.) and in those not having pneumonia. Lowered vitality may invite an attack of the disease. Epidemics show that infection must sometimes take place from without. House epidemics occur, and here the disease is very limited. There may be asthenic and anasthenic pneumonia, as there may be an infective and a toxic pneumonia. The organisms possess both properties. The inflammatory exudate is a protective. The pneumonia itself is not the danger. The exudate keeps the organisms out of the body. The general symptoms, the action on the heart and kidneys and the nervous system, these we must think of as due to the specific poison. The crisis is coincident with the appearance in the blood of a new substance which kills the disease if the patient recovers. Up to this time the poison has been in the blood, but the appearance in the blood of this antidotal substance causes the crisis, and the poison is no longer found there. The crisis does not cause any change in the lungs. They are just as congested and hepatized after the crisis as before. It is the substance in the blood.

Treatment.—The general treatment is altogether too mechanical. It was supposed that the congested lungs offered too great resistance to the weak heart, and the object of clearing up the lungs was to relieve the heart and help the breathing. It has been experimentally shown, by tying off a part of the lung in a rabbit, that this mechanical obstruction is not sufficient to produce the effects of pneumonia. The question is, can the immunity-producing substance be utilized to treat this disease? Experiments are now in progress to answer this question. They are not to be reported on yet. We have an opening up of a new subject that cannot fail to be of great use to medicine. The study of the chemical substances in the body, and their use in preventing and causing disease, is a very broad question. I believe we are on the verge of a new discovery.

The Surgical Care of Workmen.—Dr. Robert W. Johnson read a paper on this subject in which he spoke of the importance of surgery as applied to the working class. He discussed the operations, principally of the extremities, and urged the operations which would give strength rather than beauty, and based his experience on a large number of cases seen at the Maryland Steel Company's Works.

Dr. Randolph Winslow objected to some of the amputations on the ground that amputations higher up would be better, and would allow the adjustment of an artificial member.

Dr. Johnson replied that most of the men were not in a condition to purchase expensive artificial members.

Meningitis in Children from a Clinical Stand-point.—This was read by Dr. C. O'Donovan. The two kinds are, 1st, simple, and 2d, tubercular. The diagnosis is not easy, and is often only made after death. The diplococcus pneumoniæ has been found in the serous membranes in this disease. His conclusions were:

1. Meningitis is of frequent occurrence, and is insidious in its onset.

2. It is not amenable to treatment except at its beginning.

3. The best treatment is quiet, blood-letting, free purgation, ice-caps, bromides and iodides, and good attention. Even with this care recovery is not frequent.

Notes on the Use of Chloroform.—This was a paper read by Dr. L. E. Neale. He did not believe in the too frequent use of chloroform, but occasionally did use it to the point of obstetric analgesia. He used it in all operations. He used ergot when the uterus was empty. He was an ardent advocate of the douche.

Dr. J. E. Michael thought that Dr. Neale had struck the proper key-note. The obstetrician does, as a rule, use chloroform, and there must be a reason for this. Fordyce Barker had written a good paper on this subject. Within the uterus it has a bad effect on the child, and promotes post-partum hemorrhage. The attainment of the obstetric anæsthesia is very important, for we must recognize that there is a surgical and obstetrical anæsthesia. In some cases it may be necessary to have surgical anæsthesia, but it should not be used as a rule. Ergot, as generally used, does more harm than good.

Dr. P. C. Williams did not think that the abuse of a good article was a good argument against its legitimate use. He agreed with both speakers. It is much easier for a man to argue on this question than for a woman. He did not think that chloroform increased the difficulties of labor, and it diminished the activity of the pain. He has seen cases where the chloroform helped the child to be delivered.

Dr. Hunter Robb agreed with Dr. Neale, and did not think we should use chloroform so often except in operations. He did not think it was well to use antiseptic douches in the uterus, or even in the vagina. It causes a necrosis of the lining membranes of the genitalia, and increases the chances of infection. Keep the external genitalia as clean as you can.

Dr. Thomas Opie agreed with Dr. Neale, and thought that, as a rule, all anæsthetics were dangerous. Morphia and chloral allay the pain more satisfactorily than chloroform, and when chloroform is once given, it must be kept up for a long time. It lengthens the intervals between the pains, but there is much greater danger of hemorrhage. When there is anything in the cavity of

the uterus ergot is contra-indicated. When it is empty we may use it. He does not like the douche.

Dr. A. B. Price had used carbolic acid solutions as injections into the uterus. He did not like ergot when there was danger of post-partum hemorrhage before removing the placenta.

Dr. W. E. Moseley had never seen reason to regret the use of the intra-vaginal douche. It is certainly cleansing, and what is also very important, it makes the patient more comfortable.

Dr. Wilmer Brinton was surprised that some used ergot in the third stage of labor in such a routine way.

Dr. R. H. P. Ellis said if we want the giving of ergot to be effective, we should always give it hypodermically. He did this regularly. When he gave chloroform he had reason to fear hemorrhage.

"The Use of Morphia and Other Strong Analgesics in Gynecological Practice." This was read by Dr. Hunter Robb. The object was to point to the dangers of morphia in certain pelvic diseases.

"A Case of Extra-uterine Pregnancy. Lateral Flexion of the Pregnant Uterus Simulating Extra-uterine Pregnancy." These papers were by Dr. P. C. Williams.

"Abortion: Its Effects when not Treated at all, or Treated on the Expectant Plan." This was by Dr. J. H. Kennedy.

The Specific Action of Drugs.—This paper was read by Dr. J. T. Smith.

Dr. W. H. Welch thought the paper was very suggestive. He referred to the work done in Koch's laboratory. We have in our own bodies agents which are active poisons, and we have also their antidotes. The peptones, for example, are an active poison when inoculated into some animals, and yet they do not harm us, which shows that we must have within us an antidote which protects us. It has been thought, from some experiments performed in extirpating the thyroid gland, that that gland acts as an antidote to some body-poisons. This bears some relation to the condition known as cachexia strumipriva. An animal always dies when this gland is removed, and the removal of other glands may have a similar result. If we cultivate certain bacilli, as the tetanus bacilli, on a culture-medium made of the thyroid gland, it does not act as a poison, as it does when cultivated on other media.

The Necessity of a Public Disinfecting Station in Baltimore; and the Use of Steam under Pressure as a Disinfectant, by Dr. E. F. Cordell.

Dr. W. H. Welch thought that the subject was of the greatest practical importance, and that steam was the great disinfectant. Sulphur is often too much relied on. He told the story of how Koch was fumigated with sulphur fumes on his way from Italy to Germany, and how a cholera culture which he had in his pocket was not at all affected by the sulphur. Sulphur may destroy the germs of small-pox, measles, scarlet fever, but we know nothing of the germs which cause these diseases.

Dr. C. Birnie did not think much of sulphur as a disinfectant.

Dr. W. F. Hines said that sulphur was better when used in a moist atmosphere. In most diseases it was best to try to kill the germs before they got about. We should disinfect the patient as well as the attendants, and, where feasible, burn everything possible.

Dr. W. H. Welch did not think that sulphur fumigation was useless against small-pox, etc., and he referred to the careful work of Dr. Cyrus Edson, of New York. He used other methods, and thought that whitewash was a disinfectant of no mean power, and heat in all forms was effective. It is hard to say how sulphur acts, but it is necessary to have moisture, for in a dry atmosphere it is almost useless, and delicate fabrics are damaged by the dry fumes.

"A Consideration of Some Irregular Positions of the Child in Utero, with Illustrative Cases." This was by Dr. J. H. Branham.

"Inspection of Milk and Dairies." This paper was read by Dr. W. B. Platt.

"Concerning the Significance of Phagocytosis." "Experiments on the Anabolic Function of the Vagus." These two papers were read by Dr. J. C. Hemmeter.

Post-febrile Insanity.—This was the name of a very interesting paper read by Dr. Henry M. Hurd. This was not a new topic. It was first spoken of in 1845. There are many varieties, but one brain condition which bears no relation to the disease which produces it. These insanities after acute diseases are alike in nature. The name confusional insanity was suggested to cover all the kinds of insanity. The three principal forms are those from shock, from specific poisons, and from anæmia, nervous exhaustion, etc. Shock is a very frequent cause of this post febrile insanity. It may come from childbirth, surgical operations, etc. There may be a fixed delirium Insanity may also come from the specific poisons, from the fevers, pneumonia, uræmic poisoning, influenza, belladonna, iodoform, chronic alcoholic poisoning, and puerperal fever. The poison acts on the central nervous system. These poisons produce an active delirium which is self-limited and stops when the drug is stopped. The third cause is from anæmia and nervous exhaustion. There are delusions of fear and apprehension, perversions of taste, progressive stupidity, and general mental impairment. This may come from typhoid fever. The actual predisposing causes of the delirium are not clearly known. Fixed ideas are impressed on the brain and cause this insanity. He gave three illustrative cases, from which it was evident that we are not justified in giving any one cause to the whole class.

Out of 23 cases, 11 came from typhoid fever; in 4 the insanity was in the form of delirium, and in 7 it came after the fever was over; 8 recovered, 2 died, and 1 did not recover; 9 of the cases were surgical. Insanity may originate from delirium, and in other cases heredity plays an important part. General practitioners do not see many cases, and are apt to give a good prognosis; while alienists see many cases, and give a bad prognosis because they see so many fail to recover which the general practitioner loses sight of. Some, too, are called cured cases which have enfeebled minds.

Prolonged delirium adds greatly to the gravity of insanity. For this reason the Brand treatment of typhoid fever to reduce the fever should be advocated. Few patients treated in this way have post-febrile insanity from typhoid fever. It removes a factor of the danger. Rest is also very important after this disease. The patient should not sit up too soon, and no company should be allowed too soon, and there should be no mental strain; and above all things, such convalescents should not be allowed to go too long without food.

Therefore, the general treatment of this kind of insanity is the removal of the cause, rest, quiet, plenty of sleep, massage, good food, and no asylums, if possible.

Dr. Harry Friedenwald had seen a number of cases of acute mania after cataract operation, and it had been attributed to bad treatment of the eyes and being in the dark room too long.

Dr. H. M. Hurd was quite familiar with that class of patients, and thought the mania was due to the instillation of the atropia. He had seen such cases which got well when the atropia was stopped. He recalled two such cases. This is a toxic insanity. One case was treated for epilepsy; she had wild delirium in the night and broke everything in the room. It was found that stopping the use of belladonna, which she had been taking, cured the disease.

Dr. C. G. Hill recalled a case of insanity from belladonna, which was stopped and the disease got well. He thought, too, that post-febrile insanity was also due to some innate susceptibility of the patient. Many pass through fevers, operations, etc., and do not have this insanity. It need not be inherited. Some cases occur on the slightest provocation.

Dr. J. C. Harris asked how he had treated these typhoid cases that were followed by this delirium.

Dr. George H. Rohé was glad that he spoke of insanity following unusual causes, as puerperal fever. He had been investigating puerperal insanity and the connection of the sexual organs. Cases followed erysipelas. It is a question whether he should class here insanity from sunstroke. In insanity from operations he thought it was not from the operation, but from the woman's condition.

Dr. H. M. Hurd, in closing the discussion, had never heard of a case of post-febrile insanity following typhoid fever which had been treated by the Brand method. He classes sunstroke with the traumatic diseases; it is a meningitis. It would be of great service if the physician would bear in mind the delirial effects of certain drugs. He related a case of a man to whom physicians had given so much salicylic acid that it had made him temporarily insane, and they wanted to put him into an asylum. He was cured by stopping the drug. He related similar cases with the iodide of potash and atropia.

Diet and Exercise in the Treatment of Epilepsy.—This was a paper read by Dr. S. J. Fort.

Dr. H. M. Hurd said he had found out that the means of treating epilepsy as suggested was much better than with drugs. It was not only necessary to have a varied diet, but the time of eating should be fixed. Epileptics usually eat too often. They should eat their last meal long before they go to bed, that is, six to eight hours before. It is better, too, for them to eat only two meals a day. They should also take all their sleep at once, and not take naps in the daytime, for the unquiet rest of the day and the uncomfortable positions are apt to bring on an attack of the disease.

Some Hints on the Relation of the Sexual Organs to Nervous Disease.—This was a paper read by Dr. C. G. Hill.

Dr. H. M. Hurd said there were two opposing camps, the gynecologists and the alienists, each one thought their specialty was caused by the other. He thought that every asylum should have a gynecologist on its staff.

"A Review of the Literature of Laryngology during the Past Year." This was a paper read by Dr. S. K. Merrick.

"The Relation of Nasal Surgery to the Treatment of Nasal Disease." Dr. G. W. Thomas read a paper on this subject.

"Opening of the Mastoid Process." This was a paper by Dr. Harry Friedenwald.

"Diphtheritic Conjunctivitis." This was read by Dr. Hiram Woods.

"The Dislocation of an Opaque Lens—Nature's Rare Method of Restoring Sight to a Cataractous Patient." This was by Dr. J. J. Chisolm.

The Expulsion of an Immense Gall-stone under the Action of Chloral.—This was a very interesting case, related by Dr. P. C. Williams. He had attended an old lady, aged seventy-two, for the grippe, and she had apparently recovered. A short time after she ate imprudently, and had what appeared to be an attack of cholera morbus. He used prompt measures and everything was stopped except the vomiting. She had a slight pain over the abdominal region, and on examination he found a well-defined tumor in the region of the ileo-cæcal valve. He thought it was an intussusception. He recalled a case in which he had given forty grains of chloral every two hours for what was an intussusception, with good results; so in this case he gave thirty grains every two hours, and as the vomiting still kept up he gave it per rectum, combined with two drachms of the fluid extract of senna, and at the end of forty-eight hours she was relieved, and the daughter who was watching the case gave him on his next visit the gall-stone, which he showed to the Society. It measured $1\frac{5}{8}$ inch in length, $1\frac{1}{4}$ in diameter, and $3\frac{5}{8}$ inches in circumference. It was the largest he had ever seen. The weight was not taken. He had thought it had ulcerated through the bile-duct and had plugged up the ileo-cæcal opening, and the chloral probably relaxed the intestines and the senna hurried it on. It only showed that it was not well to be too precipitate in operating for intussusception.

Dr. A. C. Pole said that he had reported a similar case not long ago. The stone in his case weighed two hundred grains, and he had thought it was ileus, and had given extract of belladonna and podophyllin.

The Annual Oration.—At the evening session Dr. Frederick E. Lange, of New York, delivered the annual oration, on the subject of "The Pathology and Treatment of Acute Spontaneous Osteo-myelitis." Osteo-myelitis is comparatively a recent nosological conception. Chassaignac first described it, as we now understand it, in 1854, but it is of special interest to this Society to state that Nathan Smith, who flourished in 1798, described this condition; and his son, Nathan R. Smith, in 1834, in the history of his father, gave a very good description of this disease long before the French writers thought of it.

It is a disease which begins very slowly, and is often not suspected. In this country the disease is rare, and it is also rare in some parts of Germany and Switzerland. It is not often recognized. It occurs in young persons, and attacks the juxta-epiphyseal portions of the long bones. The neighboring joints are involved. In 1884 Becker described a coccus, and later Rosenbach described an organism. The type of the disease is an acute infectious disease of specific character, and Rosenbach thought that this organism was the specific organism of the disease. Krause found the same organism in carbuncle of the neck. The pathogenic organism gets into the circulation either through the skin or the intestinal tract. It may occur in a healthy subject of the growing age, and may come after injury, exertion, etc. The patient complains of pain in an upper or lower extremity, near one of the large joints, then a little time passes and the general disturbances come on.

It may assume a typhoid condition, and then the patient cannot call attention to the trouble and it is treated as if it were typhoid fever. The bone feels as if it were broken. Again it may be like acute articular rheumatism, and is a pseudo-rheumatism, and it may go on to abscess and necrosis of bone. The epiphyses of the femur may become necrotic, and we may have a chronic bone abscess, a specimen of which he showed. There is a tendency of the patient to get over the primary and get secondary affections of other bones. The system of such patients seems to be under the influence of some slow poison, and exhaustion and disintegration takes place and the rest is much disturbed at night. An operation gives the only hope of doing good.

Dr. L. McLane Tiffany was elected President for the next year, and 117 new members were added to the list.

The Cocktail Habit.—In an address before the Cambridge Temperance Association, a few weeks ago, Professor Humphry raised his voice against the habit of tippling or nipping—taking a glass now, a glass then, and a glass often; in the morning (which was worst of all), at the mid-day meal, in the afternoon, and in the evening. Even more than drunkenness, he said, this was terribly damaging to the system; it made men sodden, and was evinced in a general shakiness of the hand, sometimes of the step, and above all of the tongue—in fact, a general shakiness of all the organs. The "nippers" succumbed to slight accidents, slight illness, or slight shocks of any kind. Prick them, and the life, as it were, ran out of them. They said, "My work is hard," and they took the very means which unfitted them for good and prolonged work. By temperance in drink, he meant that nothing should be taken whatever, under any conditions, except at meals, and very little then. Those who could not be absolutely temperate, and content with moderation, should become total abstainers.—*British Medical Journal.*

AMERICAN PEDIATRIC SOCIETY.

Fourth Annual Meeting, held at Boston, Mass., May 2, 3, and 4, 1892.

THIRD DAY, WEDNESDAY, MAY 4TH.

(Continued from p. 551.)

Syphilitic Broncho-Stenosis in Children.—DR OSLER, the President, announced the absence of Dr. I. N. Love, of St. Louis, and called on DR. A. SEIBERT, of New York, who read a short paper on the above subject, describing several cases observed by him and others. A short discussion by Drs. Caillé and Jackson followed.

A Case of Death from Laryngismus Stridulus in Incipient Rachitis.—DR. ADAMS, of Washington, D. C., read a paper on this subject. The discussion brought out several interesting points, *e.g.*, that the negro was more rachitic than the white man.

DR BLACKADER asked how frequently laryngismus stridulus was met with in rachitic children in America, he furthermore adding that he had observed very few cases in Montreal.

DR. CAILLÉ stated that one cause observed by him was adenoid vegetations.

DR. SEIBERT said the probable cause of death in the case of Dr. Adams was due to enlarged thymus gland, as described in Professor A. Jacobi's work.

DR. A. JACOBI stated that rachitis was diagnosticated, but no cranio-tabes found, but he believed that out of fifty cases of laryngismus stridulus, forty nine were positively due to rachitis. He also believed that if the child had been rachitic from the beginning, that there might have been an œdema of brain, causing death. He questioned the existence of adenoid vegetations owing to absence of "snoring." He believed that in some cases of laryngismus stridulus the snoring must be looked for, and a dangerous cause may be the elongation of the tongue, and consequently its swallowing. He cited an interesting case of a child of Professor Gerhart, where death was caused by this, and where post-mortem examination showed the tongue to be lodged deeply in the throat, closing the larynx and causing thereby suffocation.

Sacro-coccygeal Tumor in a Child Three Weeks Old—Operation — Recovery, was demonstrated by DR. F. HUBER, of New York. It was proven to be a cystic growth, and the microscopical examination was made by Dr. Loudern, through courtesy of Dr. A. Jacobi.

Peroxide of Hydrogen.—DR. A. JACOBI, of New York, next read a note on this subject, describing the evil effects of same, and supplemented this statement by remarking that his attention was called to this by Dr. A. Caillé, of New York, who had attended a child with diphtheria and found that "peroxide" corroded the mucous membranes. Drs. A. Jacobi and A. Caillé finally agreed to discontinue its use, with benefit.

DR. BUSHINGHAM had used it in the Boston City Hospital with no evil results, but believed it might be purer, and hence not so corrosive as the kind used in New York.

DR. EARLE stated that he recently had seen an article in the Chicago *Tribune*, evidently by some un-informed writer, lauding peroxide of hydrogen as the great panacea for everything. He expected to have more patients as a result of this article.

DR. A. JACOBI closed the discussion.

Relation of Rheumatism and Chorea.—Discussion on this subject was arranged by the Council and participated in by Dr. C. W. Townsend, of Boston; Dr. F. M. Crandall, of New York City; and Dr. Samuel S. Adams, of Washington.

DR. ALLAN STARR, of New York, being unable to be present, sent a very interesting paper taking the neurological side of the question, and believing the neurotic element to be the main factor as the cause and requiring the treatment.

Next followed papers by Drs. Townsend, Crandall, and Adams, all very interesting.

DR. A. JACOBI opened the discussion, stating that he perfectly agreed with the views as expressed in Dr. Crandall's paper. He believed that rheumatism was not diagnosed as often as it should be, and that this was the cause that so many cases were overlooked during chorea. He believed, furthermore, that most cases of so called "growing pains" were really rheumatism.

DR. L. EMMET HOLT believed in including as rheumatism all cases of endocarditis.

DR. HOOKER asked if the subcutaneous fibrous nodules were not found connected with rheumatism.

DR. LOUIS FISCHER, of New York, stated that a child presenting symptoms of chorea was attended by him two years ago, and after a few weeks' treatment with Fowler's solution, was discharged cured. This same child called last month with a second attack of chorea, and complained of pains in the joints. Careful examination of the heart could not detect any abnormality. There was no abnormal temperature. An examination of a drop of blood taken from the index-finger, with the necessary sterile precautions, showed numbers of micro-organisms resembling streptococci. These organisms disappeared entirely after ten days of treatment with Fowler's solution. A noteworthy fact was the simultaneous disappearance of pains in the joints and the micro-organisms from blood subsequently examined. This was intended, he said, as a preliminary report.

DR. OSLER closed the discussion, adding among other things that he had found rheumatism associated with about twenty per cent. of his cases of chorea.

AFTERNOON SESSION.

The Value of Milk Laboratories for the Advancement of our Knowledge of Artificial Feeding was the title of a paper read by DR. T. M. ROTCH, of Boston. A very scientific and careful investigation, showing, for example, the bacteriological examination of unsterilized milk to contain sixty-eight thousand colonies of bacteria. It was then shown by the author that milk need not be brought to the boiling-point, 212° F., in order to be properly sterilized, but that being heated to 167° F. was ample for feeding purposes, as the following will show:

Milk.—Sterilized at 212° F.; sterile as to bacteria. Sterilized twenty minutes at 167° F.; also sterile as to bacteria.

Modified Milk.—Sterilized at 212° F.; sterile as to bacteria. Sterilized twenty minutes at 167° F.; also sterile as to bacteria.

Above is a sterile food, and not cooked.

The discussion was continued by Dr. Hooker, and also by Dr. Koplik

DR. JACKSON had made considerable bacteriological examination of milk in Boston, and found it very pure.

DR. HOLT had been disappointed in using sterilized milk. It did not accomplish what was claimed. The difference in temperature being 167° F., as proposed by Dr. Rotch, and the admirable recipe should be well appreciated. In an article written in Keating's Encyclopedia he had referred to food recipes, that they should be prepared as carefully as drug recipes.

DR. BLACKADER believed that milk sterilized at 212° F. did not give that which we desired. He believed with the Arnold Sterilizer, that it took fifteen minutes to reach the temperature of 175° F., and believed that higher temperatures altered the character of the milk.

DR. A. JACOBI said that sterilization would never make human milk out of cow's milk. He believed the principles of feeding as laid down by him and followed all his life were as good as any other kind, sterilization or no sterilization. His boiled milk was really sterilized.

DR. ROTCH, ending the discussion, said the action of lime-water and sugar of milk seems to form a chemical combination at 212° F., which is not the case at 167° F. Milk at 167° F. was not sterilized, but Pasteurized.

A Simple Method for Clinical Examination of Breast-milk, was the title of a paper with demonstrations by Dr. L. Emmet Holt, of New York. He presented Professor Feser's lactoscope, and also showed Marchand's. Next followed a demonstration of a lactoscope devised by himself for examination of milk. The sample taken for examination should be from the middle of the nursing or when the breast has been about one-half emptied, as the first milk is always poorer and the last richer than the average. About half an ounce is required. The specific gravity should be taken at a temperature of from 65° to 72° F. By giving the stem of the lactometer a twirl as it is introduced it readily settles to the proper level, which may otherwise be prevented by the adhesion of the milk to the glass, especially in a rich specimen. The cylinder for cream test should be filled exactly to the top of the scale. After twenty-four hours the percentage of cream is read off, each degree in the scale being one per cent. A temperature ranging between 60° and 75° F. should be maintained. Note that the quantity of milk must be determined by other means; milk may be average in quality and very scanty.

Human Milk.

	Specific Gravity 70° F.	Cream—24 Hours.	Proteids.
Normal average	1.031	8 per cent.	1.5 per cent.
Healthy variations	1.028 to 1.029	9 to 12 per cent.	Normal (rich milk)
Healthy variations	1.032 to 1.033	5 to 6 per cent.	Normal (fair milk)
Unhealthy variations	Below 1.028	High (above 10 per cent.)	Normal or slightly below
Variations	Below 1.028	Normal (5 to 10 per cent.)	Low
Variations	Below 1.028	Low (below 5 per cent.)	Very low (very poor milk)
Variations	Above 1.033	High	Very high (very rich milk)
Variations	Above 1.033	Normal	High
Variations	Above 1.033	Low	Normal (or nearly so)

Milk presenting only moderate variations from the average, *e. g.*, sp. gr. 1.028, cream four per cent., or sp. gr., 1.033, cream ten per cent., can usually be modified by appropriate treatment. If, however, the sp. gr. is from 1.018 to 1.024, and cream only two per cent. to three per cent, it is hopeless.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON SURGERY.

Stated Meeting, March 14, 1892.

Joseph D. Bryant, M.D., Chairman.

Epithelioma of the Lip.—Dr. W. E. Porter related three cases and presented two patients, illustrating operations for the removal of extensive cancer of the lower lip. The first case was that of a man, aged seventy-one, farmer. His grandfather had cancer of the cheek, removed by operation. His mother died of cancer of the breast at the age of fifty. A cousin died of cancer of the breast. He had never used a pipe nor irritated the lip in any way. No specific history. In August, 1890, he first noticed what he supposed was a small blister on the lower lip. Later a scab formed and increased in size, so that at the advice of friends he visited two quacks who applied plasters and pastes, with the result of hastening the growth. Considerable pain and some hemorrhage. On admission to the hospital a cauliflower growth was present, measuring five inches in length by three inches and a half in breadth, situated on the lower lip and extending beyond the angle of the mouth on both sides. The surface presented a foul, ulcerating area. Operation under ether, August 21, 1890. Vertical incision, some distance beyond the angle of the mouth, was made on either side, the two united by a transverse incision below the lower border of the inferior maxilla, the growth and adjacent portions of cheek and lower lip were dissected away. The only available space from which sufficient tissue could be obtained to fill in the large space remaining was from the upper portion of the cheeks. Repair was made after the method of Von Brüns. An incision was made on either side from a point about one-half an inch beyond the angle of the mouth upward and inward toward the nose, about three inches; then at right angles in an upward and outward direction two inches and a half. Then an incision was made downward parallel to the first. The flaps were dissected loose and turned down so as to form the lower lip. To form the vermilion border, strips of mucous membrane were dissected subsequently and attached by catgut. Silk sutures were used everywhere except for this purpose. The patient was discharged cured September 22, 1890. The lip presented a good appearance when shown; there had been no recurrence.

The second case occurred in a man, aged thirty-nine, admitted to the hospital January 13, 1892; family history negative. Three years ago he cut his lip with a chip, which left an irritating sore. This remained stationary about two years, but the third year increased very rapidly until it involved most of the lower lip. In this case Malgaigne's operation was performed, January 15th last, the growth being removed by two vertical incisions, extending down about an inch and a half from the angle of the mouth, and united by a third horizontal incision below the border of the tumor. Two parallel horizontal incisions were then made on either side and the flaps from the cheeks brought into place by the sliding method and secured by silk suture. The mucous membrane which had been removed at the same time was stitched in place with catgut. A large fold was left in the cheek above and without the angle of the mouth and another below the lower incision, both being remedied by removing a V-shaped piece of integument. The sutures were removed on the ninth day, and the patient was discharged February 10th. Good result.

The third case occurred in a man aged fifty-three, giving a family history of cancer. The operation in his case was similar to that in the second case, and was performed July 17, 1891, with good result.

Dr. Armstrong said he had operated in a few cases of epithelioma of the lip in the manner described by Dr. Porter. It was a good method. He inquired of Dr. Porter whether he had had any experience with pyoctanin.

Dr. Porter replied that he had used pyoctanin in some cases of cancer of the breast, the only result being that it had prevented so rapid ulcerative process.

Dr. Willy Meyer had in 1891 removed about the whole of the lower lip for epithelioma in one case, with good result, no recurrence yet.

The chairman said his experience in removal of the entire lower lip for epithelioma had been limited to two cases. The result had been good.

Fibrous Tumors of the Breast.—Dr. C. N. Dowd presented five specimens, removed by different operators, illustrating fibrous tumors of the female breast. Later he read a paper on this subject. In the case of the first specimen the breast had been enlarged about four years. An incision brought away a cyst the size of a pea, and removal of the one breast showed that it was a collection of like cysts and of fibrous tissue. The other breast was removed afterward and was found in a similar condition. In the case of the second specimen the enlargement of the breasts had been noticed only six months. On removal they were found to contain many cysts with an opaque fluid. The third specimen presented general induration throughout the breast and a few small cysts near the surface. It was a typical case of simple interstitial mastitis. The fourth specimen was very similar, but contained some abscesses with necrotic walls. The fifth specimen was a tumor of the scalp, which was presented to show that a fibrous tumor if allowed to remain might take on a malignant nature. The woman had had several growths on the scalp for some years, and last summer

one became painful and was removed, and proved to have changed into an epithelioma. It reached down to the pericranium.

Multiple Tendon and Nerve Suture.—Dr. Lilienthal reported a case of this character which he made a basis of some remarks. It occurred in a boy four years of age whose right wrist was cut by a piece of glass. A dish-cloth had been wrapped about the wrist. Afterward a physician saw the case and tied the divided artery, and still later the boy was brought to the dispensary. He was told to report the next day, prepared for anæsthesia. They then found that most of the palmar tendons of the wrist, one of the arteries, and the nerves had been cut through. The central end of the median nerve was freshened, the distal end was not, while both ends of the ulnar nerve were freshened before uniting them. They were so small that it was necessary to pass the suture through the nerve, not alone through the sheath. Regarding the tendons, he could only make approximation of apparently corresponding parts. At the end of forty-eight hours it was necessary to redress the wound, and the result was that the nerve sutures held while the others did not and the tissues healed in one mass. There remained an absence of sensation over the distribution of the median and radial nerves, the hand was pale or blue and cold, the arm much wasted. A second operation was undertaken, he excised the scar, and an attempt was made to free the tendons, which was most successful with regard to the upper ones, while the deeper ones had to be left to themselves. The median nerve was also exposed, the ulnar was not. Primary union followed, and massage and Faradisation were patiently and persistently applied by Dr. Richards. Gradually sensation and motion returned, and to-day the hand and the several fingers were used about as freely as the unaffected member. Indeed the boy was still right-handed. The size of this hand was smaller than that of the left one.

The author gave a brief account of two similar cases treated successfully by Dr. Gerster. A comparison of the three cases emphasized the duty of the one first called to stop hemorrhage, enforce cleanliness, and overcome shock. His case showed that suturing of divided parts might prove successful, even where there was suppuration. It showed that one might be able to bring the distal end of a tendon into view by passive motion or "milking" the sheath. In transverse wounds, if an operation for restoring the parts had to be delayed, a longitudinal incision through skin and fascia might increase the efficiency of antiseptic measures. His case showed the value of Faradism and passive motion, but most reliance would have to be placed on voluntary motion when this became possible. He asked whether it was not possible that division of the nerves made suppuration or sepsis more likely.

Dr A. G. Gerster said that this was another case showing the error of the statement that secondary suture of divided tendons and nerves was without result. He had himself done the secondary operation in three cases, in all with a good result. A great deal depended upon the care and persistency of the after-treatment. By faradism and massage the tendon, held in a mass of granulation tissue, could finally be induced to frec itself.

Dr. Benjamin Sachs said, that the case was very encouraging, and would lead neurologists to give a more favorable prognosis in severe nerve injuries, as to restoration of sensation, and also of motion, than they had been inclined to do. While some had once supposed that the electrical current made transmission of nerve power more easy, he thought it was to-day generally admitted that the benefit came only by causing exercise in a part which could not be exercised by the will.

The Chairman inquired of Dr. Sachs what answer he would give the question: Would division of a nerve render the parts more liable to sepsis?

Dr. Sachs replied that he had avoided that question purposely. On first thought, he could see no reason why the nerves should have any influence on the septic or aseptic condition.

Dr. B. F. Curtis spoke of the necessity for the one first seeing the case of thoroughly cleansing the wound, and of testing the function of the parts beyond the division to determine whether more energetic surgical measures would be necessary. While in the case related only the more superficial tendons were liberated at the secondary operation, he thought the irritating effect of the operation had probably caused absorption and thereby set free the deeper tendons as well. The youthfulness of the patient had been in his favor. The case was also interesting in showing that good results might follow passing the suture through the nerve itself where it could not be limited to the sheath. He had recently had a case illustrating the same point, although it was too early to speak of ultimate results. In incising a tendon-sheath let it be on its side rather than on top, so as to favor drainage, and that subsequently friction of the tendon should not be directly against the cicatrix.

Dr. Willy Meyer impressed the necessity of uniting like parts. In one of two cases under his care the functional result was good. In the second case the wound was aseptic and healthy at first, but the hip- and knee-joints became inflamed, then the wrist-wound took on suppuration and impaired the result. After many weeks the man left the hospital able to partially flex the fingers.

Dr. R. T. Morris thought separation of large nerves had nothing to do with suppuration. It was the sympathetic system which controlled the capillaries.

Dr. Reginald H. Sayre had more faith in electricity than Dr. Sachs seemed to have. He had used galvanism to involved parts, obtaining results which he attributed directly to the effect of the galvanism and not alone to the muscular gymnastics which it induced. Yet faradism would cause gymnastics, which the parts would not otherwise get.

The Chairman recalled the teaching of Alonzo Clark, that to-and-fro movements with friction would cause disappearance of adventitious tissue.

Dr. Richards said he had had another case besides the one reported by Dr. Lilienthal which forcibly illustrated the value of faradism and passive motion in restoring voluntary motion in injured parts. In the second case the patient, a workman in a brewery, was thinking of having the arm amputated, yet by the methods mentioned in the course of a year and a half he regained almost full use of it.

Intra-urethral Chancroid. — Dr. Ohmann-Dumesnil (*St. Louis Medical and Surgical Journal*, December, 1891), divides chancroid of the canal into, 1, those of the meatus; 2, urethral chancroid, and 3, intra-urethral chancroid. The first is not of infrequent occurrence. In the second variety we have a condition which to all appearances begins as a chancroid of the meatus, the infection proceeding into the urethra. In the third variety, of which a case is reported, we have a totally different state of affairs, and one, in the author's experience, which is rare. Here the sore is at some distance from the meatus and entirely unconnected with any other lesion. The pain on urination is intense, there is a constant pain at the point back of the corona, and a discharge which might be mistaken for a gonorrhœa. In the case reported it was supposed that the virus had been carried in by the nozzle of a syringe used for prophylactic injections.

Hypnotism has its greatest use, Dr. Collins says (*New England Medical Monthly*, April, 1892), in the various paralyses, hyperæstheses, contractures, spasms, convulsions, and other nervous ailments of non-demonstrable organic lesions. Supposed diseases, dread of diseases, disorders of digestion, and other functions will undoubtedly in many instances disappear under the influence of mental suggestion.

Correspondence.

FIBRIN FERMENT AS A STYPTIC—A CLAIM FOR PRIORITY.

To the Editor of the Medical Record.

Sir: While I realize that it is a little late to refer to an article which appeared more than two months since, I wish to call attention to an editorial commenting on an article by Dr. A. E. Wright, in the *British Medical Journal* of December 19, 1891. The comment referred to, headed "A New Styptic," appeared in the Medical Record of March 5, 1892. My apologies for this late reference are, that having never seen the article by Dr. Wright, and the comment thereon until to-day, I desire to enter a claim of priority, or at least of independent originality, in suggesting the use of fibrin ferment as a styptic and in employing it experimentally. In November, 1891, I suggested to the Professor of Physiology of the medical college in Nashville, Tenn., which I was then attending, and to the class through him, the possibility of the employment of the fibrin ferment as a styptic in hemorrhage, and particularly in hæmophilia, by injection near the bleeding-point or administration internally. Subsequently I tried the effects of the ferment, as obtained from fresh blood, on several of the smaller animals, though with negative results, until—following the suggestion of Arthurs and Pagès, that the coagulability of the blood depended largely on the amount or proportion of lime salts—the addition of a small percentage of a soluble calcium salt to the solution of the ferment in water (preferably the chloride, from its convenience and easy solubility) resulted in the formation of a styptic which is both efficient and free from the objections urged in case of those ordinarily employed. It acts in accordance with the principles which are efficient in the physiological process, and confines its effects wholly to the blood. While I have not yet determined the practicability of forming a solution of the fibrin ferment which could be kept available in case of emergency, when the hemorrhage is obstinate or long-continued it could be obtained in comparatively short time from the blood of any animal, by coagulating the fibrin and macerating this in water. It has also occurred to me that this ferment, as well as pepsin, might be isolated without impairment of its efficiency. This I should like to suggest to the pharmaceutical chemists.

In a communication to *The Nashville Journal of Medicine and Surgery*, which was written in March but did not appear until the May issue, I again called attention to the employment of this means, although, as I was not then aware that it had been suggested by others, I made no reference thereto. I consider the matter of sufficient importance to desire the credit of a share at least in its introduction, and in view of the dates given, believe that I am entitled to a fair amount, in spite of my omitting to read the current literature until two months late.

I am yours very respectfully,

Robert C. Bicknell, M.D.

Murfreesboro, Tenn., May 7, 1892.

Tumenol, a newly-introduced substitute for ichthyol, has been found by Neisser to possess marked reducing properties, and, after two years' experience, he thinks it will prove of value in moist eczema, superficial ulcers, excoriations, etc.

Burned Flour as a Dry Dressing for Ill-conditioned Wounds, Erysipelas, etc.—Dr. J. J. Crow, of Carrollton, Ill., writes: "I have lately used common flour burned in a stove-pan as a dressing for erysipelas, senile gangrene, and burns, and am much pleased with it. It is almost everywhere present, and may be prepared in a few minutes. It is cheap and may be impregnated with iodoform, aristol, or other antiseptics. I hope the profession will give it a fair trial. It is, of course, finely divided charcoal.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending May 14, 1892.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	16	2
Scarlet fever	225	26
Cerebro-spinal meningitis	3	7
Measles	758	36
Diphtheria	104	20
Small-pox	4	2
Varicella	0	0
Pertussis	0	0
Erysipelas	0	0
Leprosy	0	0
Mumps	0	0

Gelsemium as a Therapeutic Agent.—Dr. John Aulde, of Philadelphia, writes: "The true position of gelsemium in therapeutics is not so well known as it should be. Some physicians have been loath to employ it because it was claimed as the discovery of so-called 'Eclectics.' Even the writer of these lines has been accused of reading 'eclectic' literature because, forsooth, he had the temerity to recommend the remedy for the relief of 'a bad cold;' but he pleads 'not guilty.' Last winter he had the pleasure of forming the personal acquaintance of Dr. Joseph D. Mitchell, of Jacksonville, Fla., who communicated to him an interesting account of his efforts to bring gelsemium to the attention of the medical profession. He began to make the tincture on a large scale (a barrel at a time) about thirty-five years ago, the first consignment being sent to an extensive drug establishment in Boston, with whom he had dealings. Previous to that time it had been employed as a remedy, in the lower portion of Louisiana, in connection with Peruvian bark, in the treatment of fevers, and was believed to be a valuable drug for the reduction of fever A saturated tincture was made from the green roots, and, owing to some physicians using rather too large dosage, but little demand occurred, and the first barrel lasted five or six years. Later there was a demand for five or six barrels in the course of a year, and then its preparation passed into the hands of the drug trade, and Dr. Mitchell discontinued its manufacture. Gelsemium is a cerebro spinal sedative; it lowers blood-pressure, decreases the frequency and modifies favorably the character of the pulse in fevers, and thus favors re-establishment of the normal secretions. Unfortunately, physicians have gotten into the way of using this remedy in the form of the tincture, the dose being five to ten drops. The writer is of the opinion that alcoholic solutions of this strength should be avoided, because the alcohol is calculated to counteract the effect of the drug and mask the condition of the patient. It should be given preferably in the form of a tablet triturate made from an assayed product; in the absence of this, a solution in water of an assayed fluid extract can be used, by adding the water to a measured quantity of the drug. Small doses at short intervals produce the best results; in case five drops, given in divided doses in the course of five hours, do not produce some of the physiological effects of the drug, the preparation should be abandoned as worthless."

Post-Graduate Congress for German Army Surgeons.—An order has been issued establishing a course of lectures of three weeks' duration, to be delivered at the end of each semester in all the German universities for the benefit of the army surgeons. The object is to keep them thoroughly posted in all advances made in medicine and surgery, and for this reason attendance on one course each year is made obligatory upon every army surgeon.

Brains vs. Drugs.—I am sure at the present day we are too likely to forget that the highest position we can take is to cure people by advice rather than by drugs; to make the public pay for the use of our brains, and not for so many ounces of physic. Drugs have their own field, but they are our instruments only; of themselves they have no vitality, and a sound common sense—may I say a robust physiology?—has a larger mission even than they in the treatment of disease. There is a time to give drugs, and even to give them with a free hand, but there is equally a time when advice only is needed, and not physic—shall I stop there?—no, when to give drugs is quackery! Yes, there are times when to give medicine is to give poison, for it sends the poor patient on a hunt for health which no physic will procure, and it lets slip the opportunity.—Dr. Goodhart.

Some Points in Hepatic Surgery.—The last meeting of the London Medical Society was devoted to hepatic surgery. Mr. Knowsley Thornton read a paper in which he gave particulars of five cases of cholecystotomy. He maintained that a properly-conducted exploratory incision was free from risk and might give valuable information, even when no stone was found. Dietetic and medicinal treatment ought, however, to be thoroughly tried first. The ducts were as completely within the sphere of surgical treatment as the gall bladder itself. Stones of moderate size impacted in the duct were better treated by kneading and crushing between the finger and thumb, or by forceps pressure; larger stones by incision, complete removal, and after-suture of the duct-wall. In cases in which *débris* was left in the duct the gall-bladder should be opened, sutured into the abdominal incision, and drained. Where the ducts were incised and sutured a drainage-tube should be passed into the peritoneum beside the sutured duct, and the gall-bladder also drained externally. In a well-marked case of repeated attacks of gall-stone colic, with recurring distention of the gall-bladder, it was better to operate early, and before there was a chance of injury to the duct-wall by impaction, and before the stone had reached the common duct. Such cases recovered rapidly, and there was every prospect that experience would show that complete intraperitoneal suture of the wound of the gall-bladder would be safe, and would become the rule when operation preceded damage of the ducts by impaction.

Dr. Douglas Powell congratulated Mr. Thornton on his powers of diagnosing even small stones by palpation, but did not agree with him that the gall-bladder was a receptacle for fluid accumulated in order to flush the ducts periodically. Dr. Ralfe urged the advantages of delaying before operating. Dr. Bristowe quoted cases in which there had been all the symptoms of gall-stones without any being present; also a case in which, at a post-mortem where they expected to find gall-stones, careful palpation failed to find any, but when the dissection was carried a stage farther, one was found impacted in the duct. Mr. Marmaduke Sheild spoke of the value of a preliminary thorough purgation. Mr. Keetley mentioned the case of a man who had had twenty attacks of hepatic colic, yet laparotomy failed to reveal a calculus, though the operation was curiously followed by recovery. The President (Mr. Hutchinson) protested against the view that gall-stones were things which, when found, ought necessarily to be removed; the indication for operative interference was the pain to which they gave rise. Mr. Thornton pointed out in reply, that he had stipulated that operation was only to be resorted to after other means had failed, and when the symptoms were severe; some cases recovered without operation, but others for want of it went on to rupture of the gall-bladder or gangrene of the duct, with immediately fatal results.

Influenza and Small-pox in England.—From the Registrar-General's Annual Summary, just issued, it appears that in London, during 1891, there were 2,336 deaths primarily due to influenza, and nearly two thousand of these occurred in May and June. The epidemic has now almost disappeared, but small-pox is slightly on the increase.

The Famine and Typhus in Russia.—A Russian physician writes to the *British Medical Journal* that the situation in Russia, appalling as it has been for some months past, continues to grow even worse from day to day. As has been prophesied by many Russian medical men long ago, in many of the famine-stricken regions there broke out formidable epidemics of typhus, typhoid, and recurrent fever (as well as of small-pox, diphtheria, scarlatina, measles, etc.), to spread ever farther and farther. At present the pestilence (especially typhus and typhoid) are raging in the following governments: Kazan, Perm, Simbirsk, Samara, Saratov, Ufa, Orenburg, Odessa, Kharkov, Tambov, Lublin, Suwalki. There can be scarcely any doubt that the advent of the spring season will cause a further aggravation of the epidemics. The *zemsky* (country councils) doctors do their utmost in their truly heroic struggle both with starvation and disease; but, most unfortunately, the financial means at their disposition are exceedingly small, and thus all their efforts and self-sacrifice remain useless. The Imperial Government, with their dishonest and ignorant officials, are absolutely incapable of rendering any effective and rational aid. Count L. N. Tolstoï utilizes the funds at disposal only in the Riazan Government, which is suffering comparatively to a much smaller extent. In November, 1891, Professor V. A. Manasseïn opened in the *Vratch* a special subscription list, all sums received being immediately sent directly to the medical men of the famine stricken *zemztvos* for the distribution of food, etc. Up to the present, however, the sums collected in that way, and contributed mostly by the members of the medical profession, have been utterly trifling.

So-called "Spontaneous Combustion."—Under this title Dr. Hartwell records a curious experience which he had recently. He was one day hastily summoned into the woods while visiting a case in the outskirts of the town in Massachusetts where he lives, the messenger announcing that her mother was burned alive. On reaching the place indicated a human body was found in an actual state of conflagration. The body was face downward and resting on the forearms, the upper part of chest, and the left knee. The rest of it was raised and held from the ground by the rigidity of the muscles of the parts. It was burning at the shoulder, on both sides of the abdomen, and on both legs. As Dr. Hartwell reached the spot the bones of the right leg broke with an audible snap, allowing the foot to hang by the muscles and tendons. The right shoulder-joint was exposed, and the intestines protruded through the burnt abdomen. The unburned clothing consisted of parts of a calico dress, a cotton vest, woollen skirt, and thick red woollen under garment. Apparently the woman—for it was a woman, forty-nine years of age, active in her habits and strictly temperate—had been burning stumps, and her clothing had become ignited. Dr. Hartwell's view is that the flesh—in a condition of unusual combustibility—had then caught fire, and had been able of itself to support combustion, and this is all that he means by so-called spontaneous combustion, viz., an undue liability of the flesh to actually burn. His view as to this condition is that it depends upon the fact that human bodies occasionally do possess this increased combustibility by reason of an unusual deposition of fat, and that age and spirit-drinking are factors, in that they aid in the accumulation of fat. The interest of the case which he records he claims to lie in the fact that it occurred in a person of middle life, by no means obese, and not addicted to alcoholic indulgence.—*The Lancet*, March 5, 1892.

Woman Dentists in Russia.—Since the opening of the School of Dentistry in St. Petersburg 135 women have matriculated, while the male students number only 84.

ON THE PRESENT STATE OF TREATMENT OF THE CHRONIC DISEASES OF THE SPINAL CORD, ESPECIALLY OF TABES AND NEURASTHENIA.[1]

BY LEONARD WEBER, M.D.,

NEW YORK.

UP to the end of the first half of this century our knowledge of the pathology of the cord was quite defective, and, consequently, there could be no rational treatment of its diseases; but during the last thirty years the advance made in special pathology, in diagnostic differentiation and early recognition of disease of the cord has been surprisingly great. Though the art of healing has by no means increased in direct proportion to our better understanding of the pathological conditions, it can yet be said that the prognosis of a number of diseases of the cord is better now than it has been. Not that we have found any particularly great and reliable remedies for the management of these diseases, but we often recognize a disease and have learned to apply such remedies as we have at a time when the morbid condition is still amenable to treatment. By a more careful study of the etiology of those diseases, as for instance the relation of syphilis to tabes, our therapeutics have also been helped. For the recognition of the early beginnings of chronic diseases of the cord intimate acquaintance with their symptomatology, as well as with the methods of accurate diagnostic inquiry into neuro-pathological conditions is requisite; and, even if the practitioner have sufficient skill for the above purpose, unless he has also opportunities for accumulating experience he will be embarrassed by the abundance of remedies and methods of cure in selecting that which might prove the most useful in the case before him. Now, in deliberating upon the prognosis of any case of chronic disease of the cord, it will be our first object to distinguish between functional and organic disease, the first dependent upon impalpable, the latter on structural changes. In a series of disorders, in spinal neurasthenia before all, in some cases of concussion of the spine, of hysterical paresis and toxic paralysis, palpable tissue-changes are generally not demonstrable. The molecular alterations are here presumably quite variable in a given series of cases, yet they may come to complete restoration many times, but not unfrequently they persist with great obstinacy, particularly in neurasthenia gravis, and in some cases structural changes may take place in course of time. In fact, time was when we looked upon spinal neurasthenia as a generally benign disorder which would readily yield to electricity and hydro therapeutics or the expurgation of uric acid from the system. I have seen quite a number of neurasthenias of the sexual variety, who have gone through the rounds of careful treatment year after year, here and abroad, but have neither been cured nor much improved. And here are two of them without syphilitic or other taint in their history, who, after five and more years of careful observation and treatment under the best possible surroundings, now show decided symptoms of disease of the cord.

CASE I.—A gentleman, aged forty-five, a man of large affairs and great powers of mental application, an indefatigable worker, but withal a man who knew how to live and take care of himself, showed the first signs of cerebro-spinal neurasthenia with sexual weakness when he was thirty-nine. After searching examination I could exclude the presence of organic disease, and diagnose the case as one of neurasthenia gravis. A proper regimen and treatment was ordered and followed strictly by the patient for about a year, when he went abroad. The above diagnosis was confirmed by authorities in France and Germany, and the treatment, with complete rest and absence of all care, continued abroad for more than two years. He is back these two years and under my constant observation. His impotency is complete, though there are no rectal nor vesical, paræsthetic, or paretic symptoms, but there are no cremaster reflexes now, one patellar tendon reflex almost obliterated, the other much diminished, his muscular powers of lower extremities considerably weakened, a short walk even producing great fatigue, and unpleasant sensations in the territory of both sciatic nerves.

CASE II.—An unmarried man, aged forty, healthy and vigorous at twenty, sexual excesses from twenty-one to twenty-six; many gonorrhœas; deep-seated stricture; cystitis; frequent nocturnal emissions, reducing his health and strength until he was finally cured of his genito-urinary disorders. From his thirtieth to thirty-fifth year treated for lithæmia and neurasthenia, and a favorable prognosis given. But for the last three years he presents unmistakable symptoms of disease of the cord, apparently limited as yet to the lumbar enlargement. In this, as in many other cases of spinal neurasthenia associated with lithæmic symptoms, it is the irritable weakness of the nervous system with its deficient innervating power that becomes responsible for the lithæmic state of the system, as pointed out already by Beard in his work on sexual neurasthenia.

While I do not deny the possibility of lithæmia causing nerve troubles, increased experience has cautioned me to admit the supposed frequency of the latter. In considering the possible success of any form of treatment of spinal disease it is important to inquire how much nerve-tissue has been already destroyed, and what might yet be preserved, restored, or regenerated. H. Müller, Brown-Séquard, Flourens, Naunyn, Eichhorst, and others have seen nerve-fibres regenerated after lesions in animals, much more readily in younger than older ones. No one has yet demonstrated the regeneration of ganglionic cells so far as I am aware. These experiments agree pretty well with the clinical observations in man, in whom lesions of the cord made both by trauma and disease can be adjusted more or less, according to the extent of the injury or disease and the recuperative powers of the individual. However unsatisfactory the prospects of a restitutio ad integrum of diseased nerve-tissues may be, there is this important point of clinical observation, that the nerve fibres as well as ganglionic cells can undergo considerable alterations without entirely losing their physiological functions. By the preservation of the axis-cylinder alone of a nerve-fibre its functional activity will be maintained, and a ganglionic cell may be reduced to a fraction of its normal circumference, and still do its motory or trophic work well enough. This has been demonstrated by Adamkiewicz (*Wien. Med. Presse*, 1883, No. 9, etc.) in an interesting case of tumor of the left half of the lower part of the cervical portion of the cord, which had compressed the ganglionic cells to about one-thirtieth of their normal cir-

[1] Read before the New York Neurological Society, April 5, 1892.

cumference without producing any great disturbance during life.

Whatever may be possible in the way of reduction of proliferated neuroglia of the cord and its vessels must take place before this substance has been transformed into that fine fibrous fibrillary tissue, as it is seen in longitudinal wavy fascicles in the well developed cases of posterior sclerosis, and other forms of chronic myelitis. Some years ago while at Berlin, Professor Adamkiewicz kindly showed me his superb collection of microscopical specimens of cross and oblique sections of the cord, taken from various cases of typical tabes, etc. I had occasion then to observe the masses of thick and wavy connective tissue which had taken the place of former substance of the cord along the various systems of fibres posteriorly, and often affecting the gray matter also. To study and acknowledge such changes, and still hope for —shall I say some wonderful retrograde metamorphosis by the application of any heroic remedies, such as violent hydro therapeutics or nerve stretching or suspension, seems very unwise indeed.

Simple anomalies of circulation, such as anæmia and hyperæmia of the cord, do undoubtedly get well, though even they have an awkward way of obstinacy, as every practitioner may observe in the not infrequent cases of neurasthenia or spinal irritation in men and women from various exhausting influences. Molecular changes, which probably underlie all functional disorders, are also capable of being adjusted; but here I must raise another point which interferes somewhat with prognosis and treatment. We can by no means identify the clinical beginning of a spinal disease with that of the anatomical changes, inasmuch as some of the latter may exist without interfering with or destroying the functional activity of the nervous elements. This point, well understood in the pathology of these diseases, has been brought forward in its important bearings on the treatment by L. Löwenfeld in a special treatise on this subject, published in 1888.

Most of the chronic diseases associated with structural alterations of the cord begin probably with molecular changes of the nervous elements only, leading to anatomical lesions in the course of time. The sooner proper treatment is instituted the better the hope of final restoration of the affected parts, and our daily clinical experience will show that what has just been said is not theoretical assumption. It would be a grave error to apply half-way measures or indifferent or so-called expectant treatment in these cases, in the belief that there will be plenty of time for energetic treatment. Dilatory inactivity, however useful it may often be in diseases of other organs, will here deprive the patient of the brief chance he has of being cured or improved. At the same time I do not wish to create the impression that in the advanced cases of chronic disease all therapeutic measures must be futile. We not infrequently succeed in bringing the pathological process to a standstill, to improvement, and even, though rarely, to a complete restoration of functions, *i.e.*, a cure in the clinical sense of the word. Such comparative success has been noted particularly in compression-myelitis, polio-myelitis anterior, spinal syphilis, and tabes. I know of a few cases of tabes of very long standing, where for the last eight or ten years the patients have had judiciously applied hydropathic and electric treatment, excellent care and advantageous changes of climate, and the disease has not progressed. In order to understand the possibility of such results we must know that close by the severely injured nerve-fibres of the affected portion of the cord there are always others less hurt or as yet only molecularly changed which are capable of restoration. By bringing the latter back to functional activity and strengthening the intact ones, the work of those that have been destroyed or grossly injured may be taken up by other nervous elements and functional disorders readjusted.

In the treatment of chronic structural diseases of the cord, tabes in particular, there are three methods of procedure which constitute our main reliance and which we put to use singly or in combination, according to the special indications of the case.

1. **Chemicals.**—For the last twenty years considerable sifting has been done in the multitude of remedies recommended, and we may safely say that we have positively reduced them to three, *i.e.*, nitrate of silver, mercury, and iodide of potassium. A number of well known observers have employed and still use nitrate of silver in cases of tabes. In the first case of typical tabes I had to treat, in 1870, I prescribed it in the following way: A gentleman, retired merchant, who did not deny having had syphilis when he was about twenty-five, had locomotor ataxia when he was sixty. The disease had been of about ten years' duration. I first prescribed specific treatment for him, because I noticed some slight cutaneous eruptions and well-marked dactylitis of one of his fingers, which, from the man's history, I thought must be syphilitic. To be sure, I have seen similar affections since in cases of tabes without any syphilitic history at all. The specific treatment being ineffectual, I put the patient on arg. nitr., gr. v.; argill. alb., ℥ j.; aqua dest., q. s. f. pil. 40. S.: A pill t. i d. The number of pills was increased until he had come up to one-half grain of the salt t. i. d., when he was ordered to stop for a week or two and then begin again. I kept the patient under the influence of the remedy for about eighteen months. It gave him neither bronzed skin nor albuminuria, but had no appreciable effect upon the progress of the disease, the patient finally dying at the age of sixty-five with the additional symptoms of cerebral progressive paralysis.

Somewhat better success I saw of the same remedy in the case of a horse-dealer who came under my treatment at the age of thirty-eight for tabes, mainly confined to the lumbar enlargement. Ataxia well marked but sexual potency retained. After taking the remedy for about a year he looked better, felt better, walked better and suffered less from paræsthesias and lancinating pains than before. At that stage of the treatment a somewhat strange complication arose, in so far as the patient contracted syphilis, for which I treated him for about another year, and then lost sight of him. I know he is dead, but whether he died of tabes or syphilis, or both, or some intercurrent disease, I cannot tell.

Allan McLane Hamilton, of this city, in 1881 also recommended the silver salts, and some others have tried hypodermic injections of acetate of silver, but the latter seems to me a procedure not particularly commendable in patients of that class, as they generally have a pretty vulnerable skin. As to the use of iodide of potassium and mercury in tabes I should like to state that, after studying the question since Fournier's and Erb's publications as impartially as I could (I refer here also to my paper on tabes and syphilis read before the Academy of Medicine, and published in the MEDICAL RECORD, April 5, 1884), and learning all I could from the extensive observations of my friends Brandis and George Meyer, in Aachen, Germany, both of whom enjoy unusual opportunities of seeing the various forms of disease of the nervous system in connection with syphilis, I certainly believe we are justified in treating a case of tabes with a syphilitic history by specific remedies. But the results of such treatment are often not as good as they might be; in general, they are the better the shorter the interval between the first infection and the appearance of spinal symptoms, and the less there is of other causes besides syphilis, and the sooner the case is submitted to treatment. The longer the space of time between syphilitic infection and the outbreak of spinal disease, the longer the duration and progress of the latter, the less is to be expected from a course of specific treatment. In all cases of the kind it will be well to combine hydro- and electro-theraphy with the specific remedies in order to increase the chances of success.

Professor Rumpf, in Marburg, whose book on "Syphilis of the Nervous System" contains a mine of accurate

observations, and ought to be in the hands of everyone interested in this subject, has had some surprisingly good results in some tabetic cases, which had been of long standing, by combined methods of treatment. With reference to the mode of action of specific remedies in spinal syphilis, we may assume that they destroy or render innocuous what is left of syphilitic virus in the system, or that they induce a retrogressive metamorphosis in the alterations of vessels, neuroglia, and meninges, but it will always be well to keep in mind what I mentioned above, that what is really gone of nerve-fibre cannot be restored. And, furthermore, it is possible not only, but pretty certain that, by a thorough course of mercurial treatment in more or less advanced cases of posterior sclerosis the progress of the disease may be advanced, and functional adjustment impeded. The iodide of potash is extensively used in chronic spinal meningitis and meningo myelitis, and often does good service here, but still more in disease of the cord of syphilitic origin, where numerous observers have reported favorable results. Personally, I have been better satisfied with the combination of mercury and iodide of potassium, *i.e.*, daily inunctions of half a drachm and more of the gray ointment, and fifteen grains of the iodide two or three times a day. In the paper cited above, I stated that the results I have had from the careful use of mercurial inunctions in over a hundred cases of syphilis that have been under my control in private practice for many years, have been quite satisfactory ; I have stuck to this mode of treatment since that time, and seen no cause for change. Of cases of cerebro-spinal syphilis it has not been my fortune to see and follow up more than a dozen or so, and I have given every one of them mercury and the iodide. Half of them are dead of paralysis or intercurrent disease, three I believe have been cured and have remained so, three others or a few more have been lost sight of. We know that the authorities are not yet agreed upon the importance of the rôle which syphilis plays in the etiology of tabes, and we are not yet able to pass judgment on the therapeutic value of the specific treatment of the disease, but we are also aware that some of the best men, like Erb, Fournier, Rumpf, Eisenlohr, Benedict, Reumont, Gowers, Schulz, Hammond, Strümpell, and others have reported favorable results and even a few cures, and, believers or unbelievers as we may be, we prescribe the iodide anyway as soon as we have reason to believe in the syphilitic history of a case. Of symptomatic remedies as are useful and often necessary to control lancinating pains, paræsthesias, cramps, and *crises spinales*, antipyrin and antifebrin have proved a blessing, and taken the place of the opiates to a considerable extent. Giving first the antipyrin by itself, I have lately followed Löwenfeld's plan and ordered antipyrin, gr. xii., antifebrin, gr. iv., m. f. pulv., such powder to be taken three or four times in twenty-four hours. With phenacetin my experience is limited in that direction ; it does not appear to be as prompt as the former. There are some physicians who order their patients to be rubbed with aromatic spirits and other gently irritating lotions. Most of us think nothing of it, but I do not know if we do not go a little too far in our doubt. Gentle irritation of the cutaneous nerves might by reflex stimulate the cord and favorably influence its nutrition relatively as well as it can be done by the faradic brush or certain hydropathic procedures.

II. Electro-therapeutics.—No other remedy has been and is applied as much as electricity in chronic diseases of the cord. From the crude way of its former use to the present rational modes of its application, great progress has undoubtedly been made, but the reports as to the curative powers of electricity are not only contradictory, but it appears to me also that the number of observers who are losing faith in its value is increasing. As late as two years ago, one of the best experts abroad in this matter, an accomplished physician and director of a large sanatorium for chronic nervous diseases, said to me that he could not boast of any curative results in locomotor ataxia, or even neurasthenia gravis, by electricity. Nevertheless, inasmuch as it can, when properly applied, relieve symptoms, and by its stimulating and tonic effects benefit the patient, he was not prepared to abandon its use. Judging from a discussion of this subject in the New York Academy of Medicine two years ago, that followed a paper read by our esteemed confrère Dr. Starr, and from more recent publications, the above opinion coincides with the experience of the majority of specialists here. The constant current directly applied takes precedence over all other methods. The electrodes employed now are generally flat, rectangular, muslin covered, of various sizes—3 by 6 ctm. for children, 5 by 10 ctm. for adults, are the average sizes. The current is passed transversely or longitudinally through the spine ; the former method appears to be more in vogue in circumscribed, the latter in system, disease of the cord. In the longitudinal application one pole is held steadily on the neck, while the other, put over the lumbar region, is gradually moved upward, resting twenty to thirty seconds on each successive place. Some authors maintain that the direction given to the current is irrelevant, nevertheless, the general rule is to apply the ascending current (+ pole below, — above) in more recent cases where there is presumably hyperæmic condition of the cord, and the descending current (+ pole above and — below) in older cases without symptoms of irritation of posterior roots. At the transverse (horizontal) application the anode only may be applied over the spine. M. Meyer, of Berlin, and particularly Erb, advise also to apply the cathode beneath the lower angle of the jaw, sliding with the anode slowly down the opposite side of the spinal column close to the spinous processes. The object in this mode of application is to galvanize the cervical sympathetic as well as the cord. I have practised it frequently. Weak currents only should be used, as stronger ones are apt to produce vertigo and a sense of fulness in the head.

Next to the strength of the current, the density in its application is of importance, and calculations of the dosage can be made according to C. W. Müller's formula, which is not a matter within the scope of this communication. This much, however, is important to note, that much weaker currents generally are applied now than in former times, and the single *séance* also reduced to about five minutes for the entire cord, and about three minutes to portion thereof. No one with any experience in giving electricity would be without a reliable galvanometer nowadays, as neither the patient's sensations nor the measuring of the strength of the current by the number of elements used are of any practical value in fixing the dosage. As to the application of the induced current in chronic disease of the cord, I am acquainted only with Rumpf's method, the application of the faradic brush. It is done in this way, that one electrode is applied over the sternum, and with the other holding the metallic brush, various places of the back and affected extremities are touched and reddened several times. Rumpf begins always with the back, thence going to the extremities, and repeating the process once ; a *séance* lasting for about ten minutes. By this form of treatment, stimulating ganglionic centres by reflex and perhaps improving nutrition by vaso motor influence, he reports to have had good results in some cases of tabes, though in many of them he had also occasion to prescribe antisyphilitic remedies. I have used his method in combination with galvanization in some cases, and been pleased with the results obtained. Of the good effects to be had by electric baths and static electricity in those diseases, a great deal has been said, but the hopes entertained in that direction have not been fulfilled.

III. Hydro-therapeutics.—In the external employment of water we have an important element in the treatment of chronic diseases of the cord, as well as in many other acute and chronic disorders. A generation ago hydropathic institutes and the like were frequently in the hands of empirics, who in their crude way of applying water on

general principles, either too cold or too hot, did more harm than good. If the action of this great and useful thermal stimulus on the nervous system is not yet properly understood, we have certainly learned by experience, in the last twenty years, a better method of its application, for we now know that high as well as low temperatures are to be avoided. Patients are treated at home or in special institutes with plain water, though they may also take natural or artificial salt-water baths, mud, or sulphur baths. Sea and river bathing, Turkish and Russian baths, have done more harm than good, and are now generally avoided. The methods in hydropathic institutes and in thermal watering-places have come to be alike, inasmuch as the cold bath, the cold douche, cold rub have been discarded, and been substituted by the cool and tepid baths from 90° F. down to 72° F., and the results of treatment are better now than they have been. For at least ten years I have followed what I believe to be the late Dr. Runge's method in cases of tabes, which consists in putting the patient in a tepid half-bath of about 85° F. for five minutes, and pouring a pailful or two of water of 75 to 80 F. gently over his back and shoulders before he leaves the tub. This may be done daily or every other day, and I know of no other plan by which I had better, or even as good, temporary or permanent relief; and it deserves to be recommended. Runge claimed to have cured some cases of tabes in this way. I have not been so fortunate, but have certainly seen marked improvement in some cases. The natural salt-water spring baths contain from two per cent. to three per cent. salt; for the artificial bath of that kind, from five to six pounds of salt to an ordinary bath-tub full of water is generally used. The patients now are kept in the tepid baths for five minutes, in the cooler baths for three minutes, generally. In various watering-places I have seen patients kept in longer, up to ten and fifteen minutes. Sulphur baths are especially recommended in spinal disease of specific origin, but nobody believes now that they could be of much benefit by themselves in such cases, but they may assist the action of antisyphilitic remedies. In sending patients with more or less advanced spinal disease, to a watering-place, it is well to remember that they do not bear well long and fatiguing journeys, and that a sojourn there of four or six weeks, embracing the usual number of twenty-four baths, does not promise much success. To obtain a fair and lasting result the patient must be prepared to stay two or three months, and longer if required, and he ought to be informed of that before he sets out on his journey.

IV. Revulsive and Mechanical Treatment.—Though the three modes of treatment we have reviewed, applied singly or combined, are those which are now relied upon in the treatment of these diseases, there are some other more or less heroic measures of which we have read, which we have tried, and with which we have failed to effect cures. There is the treatment by revulsion from the playful *points de feu* and the comparatively innocent moxæ to the burning of broad, deep stripes along both sides of the spine, which, until the last few decades, was recommended by high authorities as the best thing in chronic diseases of the cord, and practised by many physicians in many countries. Most of us here have applied the *points de feu* with the Pacquelin, some of us very much so, but I doubt if more than moderately stimulating effects and passing psychical impressions have been produced thereby. I remember two cases of fully developed locomotor ataxia which I saw in one of the wards of a German University hospital, in 1879, that had deep and destructive stripes burned into the integument alongside the spine, about four weeks before they were shown to me. The house-surgeon maintained that the ataxic gait and other symptoms were much improved at the time of my visit, in comparison to what they were before

Of diseases suitable to the revulsive treatment, those caused by spondylitis must be mentioned first, and Charcot, and recently Althaus, have reported cases in which paraplegia was relieved after applying the ferrum candens over the affected portion of the spine. Again, the various forms of meningitis, particularly pachymeningitis, also chronic transverse myelitis, may be treated in that way. Surgical stretching of the sciatic nerve was much practised for a time after the reports of wonderful success that Langenbuch claimed to have had with it. Though in a certain number of cases some improvement undoubtedly followed, it has not been lasting, and not a single case has been cured, but many have been made rather worse, and the method has now been abandoned.

In 1883 the Russian physician, Motschutkowsky began treating tabes by stretching the body by suspension, and reported on fifteen cases thus treated, of which thirteen showed diminution of fulgurating pains, paræsthesias, and ataxia, and increase of muscular power, but the two other cases got worse after suspension. Many observers here and abroad have followed this plan, but their success has been far from encouraging.

M. Granville, in 1882, recommended nerve-vibration in certain spinal disease, to be done by a "percuteur" set in motion by machinery. This procedure, as well as hypnotism tried by Bernheim, may be of value in functional disease of the cord and nerves, but a sufficient number of reports have not been published as yet of its effectiveness to justify conclusions.

It will be remembered by those who read German medical literature, that in 1889 a letter was published by a well-known German authority, which spoke of the relatively great success that a Mr. Hessing had by putting certain orthopedic apparatus on tabic patients which were to act somewhat in the manner of Motschutkowsky's suspension, but in a permanent way and with less danger and severity. While abroad in the spring of 1890, I went and saw Mr. Hessing's famous Orthopedic Institute at Goeggingen, a suburb of Augsburg, in Bavaria. I found an immense establishment, beautifully arranged in various buildings, in gardens with concert hall and theatre for the entertainment of his numerous patients, elegant restaurant, etc., the like of which I had not seen before. Mr. Hessing, the proprietor and director of all, received me kindly, and allowed me to stay and examine and talk as I pleased with such tabic patients as were then under treatment. Mr Hessing's views of the pathology of locomotor ataxia are peculiar. He conceived the idea that most cases start with disease of the osseous and ligamentous structures of the spine, affecting meninges and cord later on, in some cases perhaps at one and the same time. To be sure, on the basis of such theory, it was but natural for him, the eminent and successful orthopedist that he is, to believe that such apparatus as would support the patient's spine and provide for extension at the same time, ought also to go far in curing the spinal disease. His apparatus, similar in principle to the old-fashioned one for Pott's disease, but of improved construction, rests on the patient's hips, and reaching well up under the armpit, allows as much extension as the patient can bear. A jury-mast with head-piece is provided also and used when necessary. Hessing orders the machine to be worn day and night, if in any way possible, and the patients submit as well as they may, though many of them complained much of pain and numbness in hands and fingers, with occasional slight œdematous swelling of the same, caused by the strong pressure of the arm and supports upon extension. Hessing said to me, "I have had thus far about sixty ataxic patients in all stages under treatment, and am well pleased with my results as to local and general improvement. But as to curing these unfortunate people, that will be very hard by any mode of treatment, for it seems to me that many of them have diseased brains also, and I find it next to impossible to carry out my plan of treatment as I should like to." These remarks show that Hessing was far from satisfied with his final results, and my suspicions in this direction were also confirmed by the statement of one of the patients present, who said that he had been with Hessing more or less

steadily for two years, but had seen no one cured, and himself, though improved as to general nutrition and some of his paræsthesias, was as ataxic as the day he came.

General Management.—It is obvious that the patient's mode of life ought to be regulated. His diet must be sustaining and proper, and stimulants be used sparingly. Rapid changes of temperature affect him badly, and a sojourn in a southern climate in winter is always indicated, where it can be done. Inasmuch as the muscles can only remain in a fair state of nutrition by motion, the patient must take a certain amount of exercise, if he is capable of doing so; if not, massage applied gently and correctly may take its place. Rest in bed for several weeks or months has done a great deal of good in some cases of spastic paralysis and initial tabes. Sexual intercourse must be always restricted, and interdicted in some cases.

Treatment of Neurasthenia Spinalis.—With the consideration of the treatment of spinal neurasthenia, formerly spinal irritation, I will conclude this paper, inasmuch as other functional disorders of the cord generally undergo similar treatment. For the lighter forms, such as are observed in young people in consequence of sexual aberrations to a moderate degree, or in the state of convalescence from various acute disorders, the removal of cause, regulation of mode of life, mild tonics, combined with varying doses of bromides or other sedatives, the use of the steel sound or the Winternitz psychrophor where there is much urethral or prostatic irritation, a three or four weeks' course of mild galvanic current to the spine, the cold sponge-bath, or other suitable hydriatic procedures, will generally be found sufficient to effect a cure. When it can be done, a sojourn in the country and the use of cold baths of short duration is often advisable.

Not so positive are the results of treatment of neurasthenia gravis, as it may develop, particularly in persons with a neurotic history, after protracted influences of an exhausting kind, such as years of mental or physical overexertion, sexual excesses, and prolonged and frequent masturbation at the age of puberty. Here the entire central nervous system is often disturbed. It is true that the life of the individual is not put in great jeopardy by the vicious habit of masturbation, but is often made very miserable, inasmuch as his capacity both for work and reasonable enjoyment are very much diminished. Even in neurasthenia the molecular changes in the nerve-centres may be such that, after the removal of the causes and by applying all proper treatment, functional readjustment may not be accomplished, as I have shown by one or two cases, when speaking of the pathological features of our subject, in the beginning of this paper. Here also the various modes of application of electricity, cold-water or thermal baths, massage, moderate exercise, sojourn at the sea or in the uplands, are indicated in pretty much the same way as in cases of incipient tabes, but have to be adapted to the individual requirements of the case. While of drugs, iron, arsenic, and other tonics are often useful, the bromides, as sedatives, and antipyrin or phenacetin, as antineuralgics, are often required, we find no indication here for nitrate of silver.

Whatever progress we have made in the treatment of spinal diseases, it has not been due so much to the light furnished by the study of their etiology as by clinical observation and practical experience. Let us hope that as time goes on we may find some remedies more valuable than those we have at present.

25 West Forty-Sixth Street.

Ovid's Recipe for Wrinkles.—Take equal parts of bean and barley meal and mix with raw egg. When the mass is thoroughly hard and dry it should be ground to a fine powder and made into an ointment with melted tallow and honey. A thick layer of this applied to the face every night was warranted to smooth out all wrinkles and make the skin as soft as a baby's.

MICROSCOPICAL STUDIES IN PELVIC PERITONITIS.[1]

By MARY A. DIXON JONES, M.D.,

Brooklyn, N. Y.

Probably no disease is more frequently met with by gynecologists than pelvic peritonitis, and few have been more carefully studied as to causes, symptoms, treatment, sequelæ, etc.

From a clinical stand-point, I have long been convinced, as I said in an article published in the Pittsburg *Medical Review*, October, 1889, that in plastic peritonitis, when the tubes and ovaries are bound in with pseudo-membrane, as also in purulent peritonitis, when there are larger or smaller abscesses, in connection with, and as a result of, disease of the tubes and ovaries, the only way of permanent cure is by removal of the diseased structures.[2]

To find if possible a better way, and to learn more of the nature of the disease or pathology of the conditions, I have for months past been making, with the microscope, researches in the morbid changes, the minute anatomical features of pelvic peritonitis, and now present the results of my investigations. I am not aware that anyone has before studied the subject microscopically.

To secure definite results in the microscopical examination of any tissue, the first necessity is a proper preparation. After working for more than fifteen years in microscopy, I am convinced that the best method is: First, harden the specimens in one-half of one per cent. of chromic acid, which gives a distinctness that cannot be secured by any other preparative fluid; then, after thin sections are made, mount in chemically pure glycerine, and not, as is the usual way, in Canada balsam, which so clears up the specimen that it cannot be satisfactorily studied with high powers of the microscope; while specimens mounted in pure glycerine, after previous hardening in chromic acid, are fit for the finest definition by the highest powers of the microscope.

The almost universal method of mounting in Canada balsam has probably put back the progress of pathological investigations more than twenty years. Recently some microscopical slides were sent me from a well-known university. They were beautifully mounted, but done in Canada balsam, and I could scarcely recognize my old friends, endothelioma and gyroma; and certainly from specimens so prepared I could never have defined and learned the peculiar changes characteristic of these two diseases.

In this article I will give, first, a description of the normal peritoneum as I have studied it microscopically, and note certain anatomical facts which seem to have escaped the attention of previous observers; second, the pathology of inflammation; third, describe the morbid changes of peritonitis in the various constituent parts of the peritoneum, viz., endothelium, connective tissue, blood-vessels, and smooth muscles; and fourth, the etiology of peritonitis.

The peritoneum is a connective-tissue formation, closely attached to the organs of the abdominal cavity, most of which are entirely, others partially, covered by it. The free surface of the peritoneum is covered with a layer of so-called endothelium (Fig. 1).

Endothelia are polyhedral, nucleated, protoplasmic bodies of greatly varying sizes, and separated from each other by a narrow, light ledge of cement substance. They are claimed to be connective-tissue formations by German and English histologists. The distinction between endothelia and epithelia is artificial and lacks logic and consequence. They are similar in structure and functions, and appear alike under the microscope. At the fimbriated extremity of the tubes they unite and are contin-

[1] Pursued in Dr. Charles Heitzman's laboratory.

[2] William Duncan says, in the British Medical Journal: "Nothing short of abdominal section will cure. The old method of treating dilated tubes by tapping per vaginam, or by electricity, is not only unscientific, but more dangerous than abdominal section." Doran, in the same journal, says: "Abdominal section is more satisfactory, and even safer, than palliative measures."

uous; also in the liver the epithelia join the endothelia of the capillaries, and are in direct connection with them. Waldeyer has shown the covering layer of the ovary to be true epithelium, which he traces to the embryonal development of the germinal epithelia.

Nitrate of silver renders the cement substance of both endo- and epithelia dark brown. These dark brown lines, if viewed under high powers, appear dotted and interrupted, the light interruptions corresponding to delicate thorny projections of the protoplasmic bodies, traversing the cement substance, and known as thorns or

"prickles" for the last thirty years. They are a continuation of the reticulum of living matter within the epi- and endothelia, and represent the inter-communicating links between the single epi- or endothelia.

The fine net-work of living matter in each endo- and epithelium gives to the little formations their wonderful vital properties. These apparently shapeless masses of protoplasm perform some of the most vital physiological functions. All gland structures are formed of epithelia, and every secretion is elaborated by them. Each epithelium is a laboratory in itself, selecting and combining with marvellous skill.

In the kidneys they make a most complex structure, working with the same exact precision. In the bronchial tubes the millions of moving cilia do their ceaseless work, and so help in the great function of respiration. Similar epithelia carry safely the embryo of the future being through the Fallopian tubes. In the ventricles of the brain, and in the central canal of the spinal cord they have an equally useful purpose. Equally marvellous is the work of the endothelia lining the blood-vessels, or the mill ons which cover the vast peritoneal membrane.

We notice in the cement substance, at some of the intersections of the endothelia, openings or rings, as shown in Fig. 1. The stomata or stigmata are the open mouths of the lymphatics, since the whole peritoneal cavity is regarded by some as a lymphatic sac.

Beneath the endothelia of normal peritoneum is the layer of fibrous connective tissue, which is divided into two portions. The one nearest to the endothelia is made up of more delicate fibres, and abounds in capillary blood-vessels, whereas the deep layers are built up of coarse bundles, and hold arteries, veins, and capillaries, but a scantier supply than the upper layers. In the peritoneum of the broad ligament are found many smooth muscles from the ligamentum teres, which is largely composed of smooth muscle-fibres, and blends with the connective tissue of the various organs of the peritoneum.

Inflammation.—Pathologists have held varied and opposing views as to what *inflammation* is, and what are the minute anatomical changes in the morbid process. For twenty-five years the theory of Cohnheim, that inflammation is an emigration of colorless blood-corpuscles, has been generally accepted, and is still maintained by many of the best pathologists, though it has been repeatedly disapproved. Cohnheim held that inflammatory corpuscles were an aggregation of emigrated white corpuscles, and that the tissue took no part in the inflammatory process.

It is true that the most intense inflammation is near the blood vessels, the source of nutrition, and consequently there we always find the greater number of inflammatory corpuscles or protoplasmic masses. But does it therefore follow that these masses of living matter, many of which are considerably larger than the calibre of the vessels, have emigrated from the vessels?

We frequently find nests of inflammatory corpuscles where muscles or other tissues have broken down, and yet there are no blood-vessels in the immediate proximity. Even if these masses were emigrated leucocytes, could these emigrated leucocytes break down the tissues? As I have studied inflammation with high powers of the microscope I could never recognize inflammatory corpuscles as extravasated leucocytes. The most conclusive proof of the incorrectness of Cohnheim's theory is seeing the blood-vessels themselves breaking down into inflammatory corpuscles.

Inflammation, by the humeral pathologists, was also regarded as a disturbance of the vascular system. Rokitansky held that inflammation was a disease of the blood, that inflammatory and pus corpuscles originated from the exuded plasma, and this exudate became organized and produced pseudo-membranes, or hyperplasia of inflamed tissues. Virchow recognized that some tissues, such as cornea and cartilage, though devoid of blood-vessels, were often the seat of inflammation, hence he asserted that the blood vessels took but little part in the inflammatory process, but that the latter essentially consisted in division and subdivision or proliferation of the stable or fixed cells of the connective tissue, from which originated pseudo-membranes, hyperplasia, and pus. But even Virchow's theory does not explain or account for the presence of the multitude of new elements in an inflamed tissue, which could not result simply from a division and subdivision of the cells.

Attention has recently been called to the complex changes of the nuclear stroma, leading to a division of the nucleus, which changes are called indirect division by Karyokinesis, or Karyomitosis (Klein). This theory confirms at least that the cells multiply and assume varied forms, and it has induced many German pathologists practically to abandon the theory of emigration, and to return to the original views of Virchow.

If we study the inflammatory process under the microscope, we can see clearly that the tissue itself breaks down into protoplasm, that there is an increase of living matter, and some of the coarse granules form homogeneous lumps, or large masses of protoplasm, from which are developed inflammatory corpuscles.

I have watched these changes in various tissues, repeatedly seen them in the peritoneal membrane, traced the increase of living matter, the multiplication of tissue elements, and the formation of the inflammatory corpuscles. This increase of living matter is a natural consequence of the larger supply of blood, corresponding to the familiar and clinical description of "redness and swelling."

These newly formed protoplasmic masses or inflammatory corpuscles, when examined under one thousand or twelve hundred power, show a fine reticulum, and we also see they are interconnected by thorny projections or delicate conical offshoots through the cement substance.

As early as 1873, Dr. Charles Heitzman showed that the basis substances of connective tissue are endowed with life, the same as the protoplasmic bodies themselves. When from some irritation there is a liquefaction of the solid parts of the basis substance, and the protoplasm therein is set free, there will also be in this protoplasm an increase of living matter, just the same as in the epi-

or endothelia, or in the original protoplasm of the so-called "cells." The protoplasm sprung from the "cells" and that from the basis substance is the same, and both alike develop into inflammatory corpuscles. If the latter remain interconnected, they gradually become spindle-shaped, and by a reformation of basis substance new connective tissue is produced. This constitutes "plastic" or "formative" inflammation. If, on the contrary, the connections or offshoots between the protoplasmic masses is broken, then inflammatory corpuscles become pus corpuscles, and suppuration commences, resulting in destruction of tissue. Pus is not tissue, and cannot produce tissue.[1]

Professor Stricker, of Vienna, originally held that all inflammatory corpuscles were pus corpuscles, and that inflammation and ulceration were identical. Every day clinical experience shows that only a limited number of inflammatory processes is suppurative; the greater majority are plastic and lead to an augmentation of the tissue involved. Since 1880 Professor Stricker has sustained the views as taught by Dr. Heitzman, that in so-called plastic or formative inflammation the newly formed inflammatory elements remain interconnected, thus being able to produce new tissue by a reformation of the basis substance; while if the connection is broken between the inflammatory corpuscles, they become pus corpuscles.

Recognizing these facts, which are borne out in the whole history of inflammation, the formation of pus corpuscles, and the difference between pus corpuscles and inflammatory corpuscles becomes clear, simple, and comprehensive.

In studying peritonitis we see repeatedly the formation of protoplasm, the increase of living matter, the change to inflammatory corpuscles, the fine reticulum, the thorny projections between, or connecting links, and how, if the inflammatory corpuscles remain interconnected, they become spindle-shaped, and by a new formation of basis substance new tissue or pseudo-membranes are formed, which latter, if the inflammatory action continues, will increase and bind more firmly together neighboring organs in the peritoneal cavity. On the contrary, if the life connection between the living matter or inflammatory corpuscles is broken, they become pus corpuscles, abscesses are formed, or general suppuration commences, leading to more or less destruction of tissue.

Inflammatory Changes of the Endothelia.—"Cornil and Ranvier were the first who maintained that in inflammation the endothelia are enlarged, and their nuclei divide and become the source from which pus corpuscles are formed."

"The inflammatory changes of the endothelia of the peritoneum (omentum) has been studied more accurately by H. Kundrat (*Medic. Jahrbücher*, 1872). He notices, first, a disappearance of the cement substances, in place of which scattered globular bodies were seen. Next, enlargement of the nucleoli and the nuclei of the endothelia followed. In recent peritonitis he found large multinuclear bodies, which greatly surpassed in size single endothelia, and in purulent peritonitis a marked new formation of inflammatory corpuscles, but probably not all of these offshoots are the offspring of endothelia. Kundrat was the first to maintain that from the endothelia of the peritoneum, in chronic plastic peritonitis, connective tissue arises which leads to the formation of vegetations, and that this process takes place in two ways: either the endothelia themselves become spindle-shaped, elongated, transformed into fibrillæ, or large nucleated protoplasmic layers, sprung from the endothelia, become directly fibrillated."[2]

[1] Hamilton, in his work on Pathology, says: 'Suppuration is the separation from the organism by a natural process of death and degeneration of such inflammatory products as have accumulated within it.' Senn, in his Principles of Surgery, says: "In suppurative inflammation of a serous membrane the leucocytes and embryonal cells are transformed into pus corpuscles, and in this way purulent peritonitis is produced."

[2] Heitzman: Microscopical Morphology, p. 420.

In the mildest cases of peritonitis the inflammatory changes of the endothelia are the following (Fig. 2):

First, the cement substance, in consequence of some irritation, becomes liquefied. The endothelia are reduced to protoplasm; they become coarsely granular; there is an increase of living matter; the nuclei are enlarged and become more numerous, and the thorny formations of living matter of the cement substance are increased in size.

Many of the granules in the protoplasm of the endothelia unite and form homogeneous lumps; some of the enlarged endothelia fuse together and form multinuclear protoplasmic bodies, in which new lines of demarcation become visible, leading to the formation of inflammatory corpuscles. If all the granules and lumps of living matter and newly formed nuclei or inflammatory corpuscles remain interconnected by delicate offshoots, the result will be plastic peritonitis.

The endothelia are not, as Kundrat supposed, directly transformed into spindle-shaped bodies. They always split up into inflammatory corpuscles before a new formation of spindles takes place. As long as the layer of cement substance envelops the free surface of the endothelia, no agglutination can take place between contiguous peritoneal layers. The basis substance is first liquefied and sets free the living matter; then there is a multiplication and division of this living matter, inflammatory corpuscles are formed, they become spindle-shaped, and then, by a formation of the basis substance, new tissues or pseudo-membranes are developed, which cause the agglutination of neighboring organs.

In suppurative peritonitis the living matter in the endothelia increases and divides and changes into inflammatory corpuscles, then the life connection between the inflammatory corpuscles is broken, they become pus corpuscles, and suppuration begins. Plastic peritonitis may be in one portion of the peritoneum, while suppurative peritonitis is progressing in another.

FIG. 2.—Acute Pelvic Peritonitis of Moderate Intensity. (× 500.) *E E*, endothelial layer; *F*, fibrous connective tissue; *C*, capillary blood-vessel.

The Inflammatory Changes of the Endothelia Lining the Blood-vessels are exactly the same as in the endothelia covering the peritoneum. They become enlarged, coarsely granular, their nuclei augment and become in-

creased in numbers. Sometimes the swelling of the endothelia of the blood-vessels, especially of the capillaries, causes a complete choking of the calibres. The capillaries are solidified and converted into solid tracts of fibrous connective-tissue. This enlargement of the endothelia by new formations of living matter, which afterward change to fibrous connective tissue, is the cause of endarteritis obliterans, leading to a narrowing of the calibre or a complete closure of the vessels. We often see in newly formed or inflamed tissue a new formation of blood vessels, sometimes a complete vascularization, especially in pseudo-membranes of recent date.

The epithelia covering the ovaries act in the same way under irritation, and are subject to similar changes, first becoming coarsely granular, the living matter increasing,

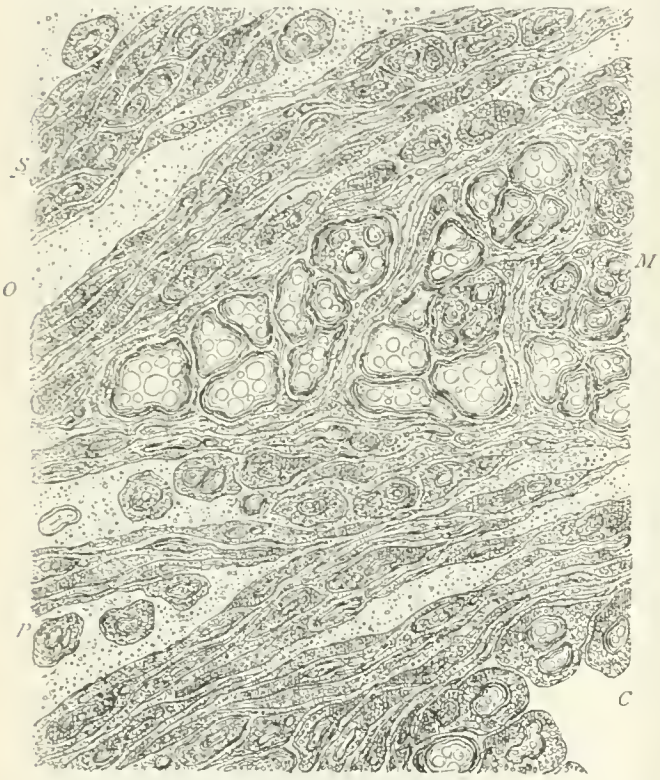

FIG. 3.—Intense Acute Peritonitis of the Broad Ligament. (×1,000.) *M*, transverse sections of smooth muscle-fibres, showing inflammatory changes; *S S*, bundles of fibrous connective tissue, broken up into spindle-shaped inflammatory corpuscles; *O*, œdema, serous exudate between the bundles; *P*, protoplasmic bodies, suspended in the serous exudate; *C*, capillary blood-vessel, showing inflammatory changes of the endothelia.

the nuclei dividing, a number of epithelia fusing together into multinuclear lumps, and then developing into inflammatory corpuscles. The latter, if the connection continues, form a new tissue, or pseudo-membranes, as mentioned above.

Inflammatory Changes of the Fibrous Connective Tissue.—In inflammation of this tissue the basis substance is first liquefied or melted out, and the bundles are transformed into more or less extensive fields of granular protoplasm, as seen in Fig. 2. The fibrous connective tissue immediately adjacent to the endothelia is almost entirely broken down into granular matter, while in the lower portion of the peritoneum there may be little change.

In more advanced stages of inflammation the original bundles of the fibrous connective tissue are reduced to spindle-shaped bodies, similar to those from which fibrous connective tissue has arisen in the early stages of its development (Fig. 3).

We see coarsely granular and nucleated spindles grouped together and retaining the original forms of the bundles. Between the groups are interstices of varying diameter, filled with coagulated albumin, or albuminous fluid, forming œdema. The spindles constituting the original bundles remain interconnected. In the œdematous interstices are protoplasmic bodies, which probably have taken origin from emigration through the walls of the capillaries.

In the third and most intense form of inflammation the bundles are transformed into chains of homogeneous, highly glistening bodies, which result from a rapid increase of living matter. held within the bundles after the preceding liquefaction of the basis substance. (See Fig. 4.)

Such solid lumps are most numerous at the points of most intense inflammation. The more intense the morbid process, the greater the change of the tissues. Sometimes whole bundles are transformed into coarsely granular protoplasm, retaining their original size and shape, or breaking up into homogeneous lumps of living matter.

The free protoplasm between the bundles of fibrous connective tissue is the first to become changed into coarsely granular, freely nucleated masses, as in Fig 2. These clusters are seen especially in the deeper portions of the peritoneum, where there is comparatively a slight although progressive inflammatory process present. In the severest forms of peritonitis the difference between the inflammatory corpuscles sprung from free protoplasm and those from the previous bundles disappear, and the whole tissue is in a condition known to pathologists as inflammatory infiltration.

Examining these inflammatory corpuscles, derived from the fibrous connective tissue, with high powers, we see in them the same fine reticulum, and the corpuscles interconnected and connecting with the surrounding protoplasm by fine, delicate offshoots. This beautiful net-work of living matter, which we find in every part and

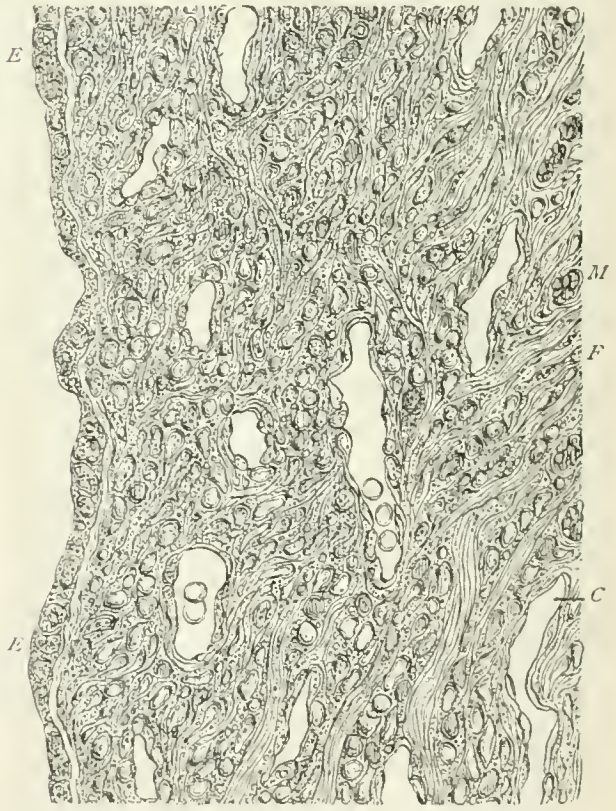

FIG. 4.—Intense Acute Tubal Peritonitis. (×500.) *E E*, endothelial layer; *F*, fibrous connective tissue; *M*, smooth muscle-fibres in transverse section; *C*, capillary blood-vessel.

in every organ, proves that the body is one complete whole, and not made up of independent "cells." It explains, too, that mysterious life-power, that inter-dependence and sympathy by which one function follows another in such transcendent order.

When, from any cause, this connection between the inflammatory corpuscles is destroyed, as probably by certain microbes, the inflammatory corpuscles become pus corpuscles, and suppuration is established.

If, on the contrary, inflammatory corpuscles remain interconnected, they, after subsidence of irritation, become spindle shaped, and, by reformation of the basis substance, form a new tissue; thus pseudo-membranes will be developed, and there will be a thickening or a hyperplasia of the peritoneum. This hyperplasia of the cellular tissue of the peritoneum, resulting from repeated attacks of inflammation, has been recognized as "cellulitis" or parametritis. Professor William Polk, in an article published in the MEDICAL RECORD, September 18, 1886, says: "Inflammatory masses under the headings of pelvic cellulitis and peritonitis are the results of salpingitis plus peritonitis."

A writer in the *Boston Medical and Surgical Journal* of July 9, 1891, gives an article on laparotomy, as he stated, verifying the diagnosis of "pelvic cellulitis." He says: "I found the tubes and ovaries in gross appearance healthy. I performed laparotomy, removing the tubes and ovaries of each side. Since the operation, six months ago, the patient has gained very much in general health and is free from pelvic disturbance of pain and discomfort." Evidently the patient had pyosalpinx, which caused the peritonitis and consequent adhesions.

In over eighty laparotomies I have never yet been able to find a mass of inflamed pelvic cellular tissue independent of the hyperplasia of the peritoneum, or the inflammatory adhesions around inflamed structures or diseased uterine appendages. With hand in pelvic cavity, I have searched repeatedly and carefully, yet have never been able to recognize an independent mass to be denominated "cellulitis."

Dr. T. G. Thomas, on December 21, 1882, when he reported his first four cases of the removal of uterine appendages, said, in referring to an article by Lawson Tait, published in the *British Medical Journal*, July 29, 1882, that "it was one of the most valuable contributions to gynecological science made during the present decade," and added: "How often has it been found that, after a long course of treatment of the uterus, including all the mechanical devices and operative procedures that the most skilful gynecologist could devise, the condition of the patient remains substantially the same, and has finally to be abandoned as incurable."

Many physicians can verify that cases of so called "cellulitis" have been treated for years without a cure being effected, while in other instances, if the cause of irritation or the source of infection be removed, the patient will in a short time be restored to health. As Dr. Grigg, President of the British Gynecological Society, in his opening address, said: "These methods have shed lustre upon gynecology as a curative art, and done much to raise it to a position approximating that of an exact science."

Inflammatory Changes in the Muscles.—Peritonitis presents an excellent opportunity for studying the inflammatory changes of smooth muscle fibres, especially in the broad ligament, or in tubal peritonitis; in the latter, we almost invariably find the muscle wall of the tube more or less invaded.

The first change in muscle fibres is that the nucleus becomes granular, divides, and there is an increase of living matter. Next, the whole muscle fibre is enlarged and reduced to protoplasm, the coarse granules arranging themselves in rows, representing inflammatory corpuscles; the small amount of cement substance between the muscle fibres dissolves, and gradually the boundary lines between the spindles disappear and the whole bundle is reduced to inflammatory corpuscles.

It is interesting to watch these progressive changes, the clearly lined muscle fibres, filled with protoplasmic masses, and ready to split into lumps. Sometimes the whole inflammatory process or destruction of muscles is clearly seen or illustrated in acute oöphoritis. In this we frequently find extended fields of intense acute inflammation, the muscle fibres disappearing or breaking up into granular matter or inflammatory corpuscles, some fibres filled with coarse granules or melting into or partly lost in large lumps of living matter; while the remains of muscle fibres scattered here and there remind one of broken pieces of plank on a wide expanse of waters.

Amid the sea of inflammatory corpuscles may occasionally be seen a bright, shining hæmatoblast—a mass of living matter, taking up the hæmoglobin from the blood, on its way to forming red blood-corpuscles. In such intense inflammation a few newly formed red blood-corpuscles are always found, and near by are frequently seen the solid or vacuoled tracts of living matter, marking out the already forming blood-vessels; while in other fields may be seen new blood-vessels winding along gracefully, showing that even in intense inflammation nature is making plans for repair. These may be the future blood-vessels of the new tissue that will grow out of the protoplasmic mass, if the connections of living matter are not destroyed. Muscle fibres when once destroyed can no more be renewed or formed again. They are lost forever. Fibrous connective tissue, being always the tissue of repair, takes its place, thus causing more or less cirrhosis. Frequently, in case of chronic or sub acute oöphoritis, large portions of the ovary are replaced by a growth of fibrous connective tissue. An ovary so changed can no longer perform its normal functions, and must to some extent be a source of distress. In like manner the muscle fibres of the Fallopian tubes may be replaced by fibrous connective tissue, the mucosa altered, the epithelia gone, and the once highly organized structure loses its fine organization, and is no longer capable of performing its full physiological functions.

Duranté and others studied the muscle changes in endarteritis, and it was shown that muscle spindles break up into rows of inflammatory corpuscles, which afterward change to fibrous connective tissue.

In inflammation the smooth muscle fibres are transformed into highly glistening lumps of living matter, appearing either homogeneous or with a varying number of vacuoles. Many of these muscle spindles coalesce into large masses of living matter after liquefaction of the intervening basis substance. In transverse sections of these muscles we meet with multinuclear protoplasmic bodies which have originated from fused muscle spindles. (See Fig. 3.) These multinuclear heaps break into inflammatory corpuscles, which closely resemble those arisen from previous connective tissue.

In milder forms of myositis the inflammatory changes are confined to, or principally take place in, the delicate fibrous connective tissue, between the groups of smooth muscle fibres. A limited number of muscle fibres may be broken up into inflammatory corpuscles, and these, with the corpuscles sprung from the connective tissue, may remain interconnected, and as in plastic peritonitis, will lead to the augmentation of the interstitial connective tissue. This process also is seen in certain forms of oöphoritis, when the cortex of the ovary will show a considerable increase of fibrous connective tissue, and a diminution of the muscle fibres.

In interstitial salpingitis we often find the most intense form of myositis. Almost all of the muscle fibres may become inflamed, and be transformed into embryonal and medullary matter, sometimes not a vestige of the original muscle fibres can be found.

Plastic Peritonitis.—Inflammatory corpuscles sprung from previous fibrous connective tissue, endothelia, or epithelia, or smooth muscle fibres, remain, as a rule, interconnected by means of delicate offshoots traversing the light interspaces between the inflammatory corpuscles. While this intercommunication remains undisturbed, the inflammatory process is termed "formative" or "plastic." After the subsidence of the inflammation the newly formed inflammatory corpuscles proceed to the formation of new tissues. The inflammatory corpuscles become first elongated, afterward spindle-shaped, and by a reformation of the basis substance develop new connec-

tive tissues or pseudo-membranes. In patients who have suffered from tubal disease, and have had in consequence repeated attacks of peritonitis, frequently the uterus or uterine appendages, or both, are not only firmly bound down but almost buried in a mass of strong, well-organized pseudo-membranes. Such conditions necessarily produce much suffering, and must shorten life.

Pseudo-membranes, when examined under high powers of the microscope, are of exceeding interest (Fig. 5).

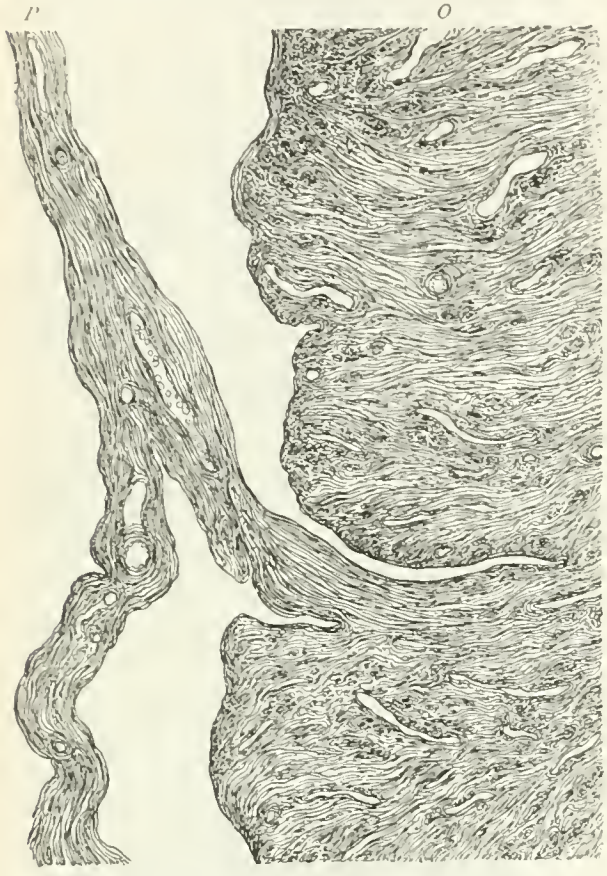

FIG. 5.—Peritoneal Pseudo-membranes. (× 50.) *P*, cord-like pseudo-membrane, with arteries, veins, and capillaries; *O*, dense fibrous connective tissue on the surface of the ovary, the result of plastic oöphoritis.

I have chosen for illustration pseudo-membranes originated from the surface of an ovary in a mild process of acute peritonitis. The ovary in this case was transformed into a blood cyst, and buried in all directions in dense adhesions, which obviously had resulted from repeated attacks of peritonitis. The septic matter from the tubes had probably caused not only the peritonitis but also the disease of the ovaries. Nearly all of the normal structure of the ovary was destroyed by the inflammatory process. The outcome of peritonitis, combined with superficial oöphoritis, was in this case a transformation of the outermost layer of the cortex into dense fibrous connective tissue abundantly supplied with blood-vessels, and but scanty vestiges of previous muscle fibres could be seen.

The covering epithelium of the ovary, as stated above, behaves in inflammation exactly like the endothelia of the peritoneum. The surface of the ovary is frequently found with papillary projections, giving to the naked eye an opaque velvety appearance. These projections are the outcome of mild attacks of peritonitis, superficial portions of the ovarian structure having changed to fibrous connective tissue.

The pseudo-membranes are made up of coarse bundles of fibrous connective tissue slightly interlacing. (See Fig. 6.) In any specimen we will see longitudinal as well as transverse and oblique sections of bundles. Between them we will find a varying amount of protoplasmic bodies, the more numerous when the pseudo-membranes are of recent date. Embedded in this tissue are a varying number of blood-vessels, arteries, arterioles, veins, and capillaries. Most of the blood-vessels are newly formed. The arterioles are characterized by the presence of a single layer of smooth muscle fibres in the middle coat. Their endothelial layer is, as a rule, pronounced and somewhat irregular. The capillaries, when newly formed, have large, irregular endothelia. In old pseudo-membranes the newly formed blood-vessels have assumed all of the features characteristic of normal ones. Often in pseudo-membranes are found amyloid or colloid corpuscles of a peculiar high power of refraction and a pronounced concentric stratification.

The newly organized connective tissues, or pseudo-membranes, were called by the humeral pathologists "exudates," and according to their views the exudates arose from the dilated blood-vessels of so-called serous membranes, which became organized and produced pseudo-membranes or adhesions, hence the term of plastic exudates is still in use by pathologists and clinicians. This view was successfully contradicted some forty years ago by Virchow.[1] We have seen clearly that the pseudo-membranes are formed by changes of living matter. They are not exudates from dilated blood-vessels, but are firmly and densely organized fibres of connective tissue, and which can hardly be absorbed by blisters on the external skin.

Frequently we find in the pseudo-membranes fields of acute inflammation. A large extent of surface may be

FIG. 6.—Peritoneal Pseudo-membrane. (× 500.) *L*, longitudinal bundles of fibrous connective tissue; *T*, transverse bundles of fibrous connective tissue; *O*, oblique bundles of fibrous connective tissue; *C*, amyloid corpuscle; *A*, artery; *E*, capillary blood-vessel.

thus invaded, or even the whole mass filled with inflammatory corpuscles. Such inflammatory attacks cause the increase of old pseudo-membranes and increased hyperplasia of the peritoneum.

In the pseudo-membranes are also frequently found foci of suppuration or miliary abscesses, as seen in Fig. 7.

Do not these suggest the possible danger of leaving

[1] A late text-book says: "The pathology of pelvic peritonitis is, first, sub-serous congestion, followed by an exudation of plastic material or the higher organized constituents of the blood. Small blisters applied to the iliac region, and repeated, favor the absorption of the inflammatory products" (Skene).

pseudo-membranes, either after removing organs or when simply separating the adhesions and allowing the organs to remain *in situ?* These foci of suppuration necessarily become sources of great peril. Besides, if organs are sufficiently diseased to produce such dense

FIG. 7.—Miliary Abscess in the Peritoneal Pseudo-membrane. (× 100.) *F*, dense fibrous connective tissue; *N*, bundles of non-medullated nerve-fibres; *A*, artery; *V*, vein.

adhesions, in most instances there is an utter destruction of their physiological functions, and, if the organs are allowed to remain, will produce new or similar adhesions.

Purulent Peritonitis.—When the original inflammatory corpuscles break asunder, we have a formation of pus corpuscles or purulent peritonitis. Under the most favorable circumstances the pus may become encysted in dense, fibrous connective tissue—harmless temporarily, but constantly a threatened danger and a continued source of irritation—and will give more and more trouble until the pus finds some outlet.

Localized superficial suppuration of the peritoneum, on account of its frequent occurrence and serious import, becomes a matter of exceeding interest. The conditions which exist in such localized ulcerations of the peritoneum are illustrated in Fig. 8.

We see the endothelia in the shape of large, multinuclear bodies, derived from the effusion of several endothelia. These multinuclear bodies first become separated into inflammatory corpuscles, then become isolated and changed to pus corpuscles. The pus corpuscles are embedded in an albuminous exudate, and in specimens are visible, as a rule, only in small numbers along suppurating surfaces, since they have become detached and are no longer objects of cutting by the section cutter.

The suppuration may extend deep into the peritoneum and even into the adjacent organs. In one instance, which I reported in the MEDICAL RECORD, August, 1886, almost the entire ovary was destroyed by the suppuration or by an abscess. The patient, when brought to the hospital, was in an almost dying condition from purulent salpingitis. The uterine appendages were removed, and thereby the patient's life was saved, and she is, to this day, in excellent health.

Etiology of Peritonitis.—Traumatism is uniformly placed as one of the causes of peritonitis, but by far the most frequent cause is sepsis or infection. A cut or tear in the peritoneum, when there is no sepsis, heals rapidly; the surgeon can scarcely keep the cut surfaces apart. Extensive wounds or the severest trauma may be inflicted on the peritoneum and no peritonitis result, as tearing away adherent uterine appendages, removing large ovarian cysts, or the operation of supra-pubic or kolpo hysterectomy. In February, 1888, I removed a uterus, enlarged by a myoma, weighing thirteen and a half pounds; then through the vagina, the stump, with the attached fibroids, thus severely wounding the peritoneum, yet the patient had no peritonitis, nor any special rise of temperature. She was up on the fifteenth day, and since has been in good health. In the same year a patient consulted me who had retroflexed and retroverted uterus, and it, with the uterine appendages, was bound in with extensive and well-organized membranes to the pelvic floor, forming on the right a large abscess which extended into the adjoining aponeurosis, the wall of which abscess was partly formed by the remains of the right ovary and tube. Only a trace of the calibre of the tube could be seen. The whole diseased mass, with the adherent uterine appendages, was removed, destroying considerable portions of the peritoneum, yet, with all this traumatism, the patient made a rapid recovery, and had no peritonitis. Adherent to the specimen were some fibres of the psoas and iliac muscles.

In another case there was a fluctuating tumor bound to the floor of the pelvis. This tumor was removed, thus tearing away a large portion of the peritoneum, besides which, the bleeding was so severe at the ragged and adherent edges of the wound that it was necessary to clamp with forceps; yet there was no peritonitis. The peritoneal cavity, as in the former case, was flushed out, and still further cleansed by being packed with gauze made aseptic by heat.

It was afterward ascertained by microscopical investigation that the growth removed in the last-named patient was a cancer of the most malignant type, and the cancerous material had infiltrated the adjoining tissues; yet with all these unfavorable circumstances cleansing the

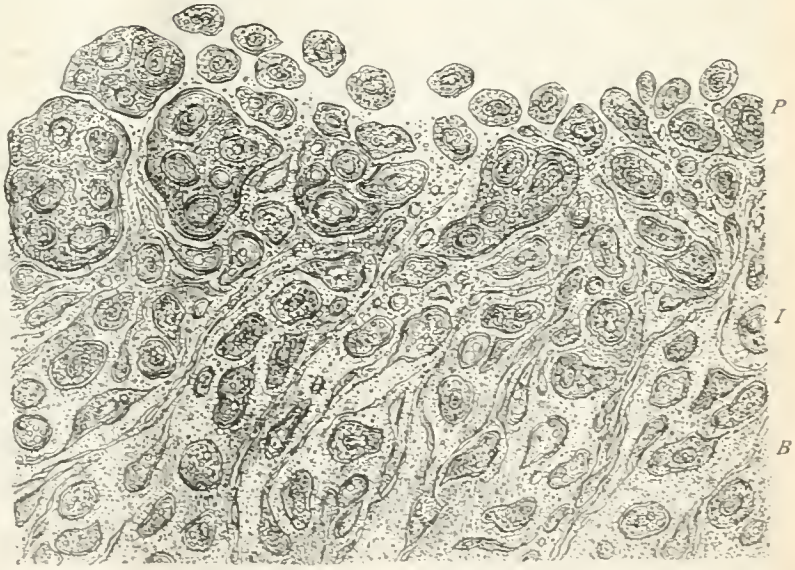

FIG. 8.—Suppurative Peritonitis of the Tube. (× 1,000.) *M*, multinuclear protoplasmic bodies, arising from endothelia; *P*, pus corpuscles, isolated protoplasmic bodies; *I I*, inflammatory corpuscles; *B*, basis substance reduced to protoplasm.

peritoneum prevented peritonitis, and the patient made a good recovery.[1]

Pathologists generally agree that the presence of some

[1] Subsequently the cancer returned, but the operation very much prolonged the patient's life.

micro organisms is necessary for the production of peritonitis. We will find that it is the pyogenic bacteria, as staphylococci and streptococci, that caused the inflammatory abscesses and death. If kept chemically pure, no tissue heals more rapidly or can safely stand more injury than the peritoneum. We see how it can endure, with apparent impunity, for years, the continued irritation of a uterus enlarged by intramural fibromata or sub-peritoneal growths.

In severe trauma, when perceptibly there is no source of infection, the rupture of the veins, arteries, and capillaries may set free pathogenic germs, and cause sepsis and peritonitis. It is a well understood fact that the blood contains various micro-organisms, as staphylococcus pyogenes aureus (Rosenbach) or streptococci citreus, albus, and flavius, discovered and described by Passet. Ogston says: "Staphylococci cause diffuse suppuration, while streptococci are found in circumscribed abscesses."

According to the researches of Senn and others these microbes, while kept in circulation, do no harm, and may be destroyed in the system or eliminated by the excretory organs. Even pure cultures may be injected directly into the circulation, or into the peritoneal cavity, and no peritonitis ensue; but if there is a wound in the peritoneum, or any part of the body, and thereby the circulation is stopped, the microbes in the blood become localized and a soil is thus afforded for the development of the germs. A person may have tubercle bacilli in the blood, and for years be in apparent good health, yet an injury to the bone may cause a localization of the bacilli, and osteomyelitis or tuberculous infection of the joints may develop. So syphilitic germs may be in the blood, ready to develop some adverse condition whenever there is a soil or localization. Whatever may be the germ of syphilis, nothing is more deadly or more apt to produce fatal results in case of an operation.

Another cause of peritonitis, or source of infection, may be an ulcerating surface in a distant part of the body, from whence the pus microbe may be conveyed.

Again, various micro organisms are often introduced by unclean fingers, instruments, etc., especially after confinement, when the abrasions and tears in the cervix and the uterine mucosa are as yet destitute of the protecting epithelium at the previous site of the placenta. This is especially the source of much trouble, and has no doubt destroyed the health and lives of an untold number of women, as so many ignorant and uncultivated midwives assume the duties of the office without previous preparation, many of whom have not the least idea of antisepsis or surgical cleanliness. Every one, man or woman, who does the work of an obstetrician should understand the principles of asepsis and antisepsis. The records of well-conducted maternity hospitals show the very great saving of life from carefulness in these respects. We could gather no such lessons from the millions of isolated cases unrecorded. The large mortality of women at the child-bearing period tells the story.

So far as is at present known, the most frequent pyogenic germs of peritonitis are gonococci. Noeggerath observed clinically the continued contagiousness of gonorrhœa, even after an apparent cure of months' and years' standing, and he suggested the plausible theory of "latent gonorrhœa," which, from a clinical stand point, was the best presentation. Scientific investigation has shown the foundation for this theory, and proved that the gonococci do remain in the system for years, and may travel to remote parts or organs. Dr. Ely [1] mentions the record of nine cases of malignant endocarditis, in which the urethra appears to have been the point of entrance of the micro organisms. Bergman found gonococci in pus removed from the knee-joint three weeks after the beginning of arthritis. The continued and irrepressible presence of these gonococci explains how the disease may be communicated years after an apparent cure.

[1] Proceedings of the New York Pathological Society, 1888, p. 160.

Soon after infection the gonococci are found in the mucosa of the uterus, and may develop gonorrhœal endometritis in the healthiest woman. Then follows gonorrhœal or purulent salpingitis; the mucosa of the tubes becomes intensely inflamed; the delicate folds increase in size, and are filled with inflammatory corpuscles; they commence to suppurate; the suppurating process may extend into and destroy the muscular walls of the Fallopian tubes; and pus may find its way into the peritoneal cavity, producing repeated attacks of suppurative peritonitis. I believe gonorrhœal infection is one of the most frequent causes of disease of the uterine appendages, and of inflammations and suppurations of the peritoneum. Nature, for temporary protection, may seal up the fimbriated extremity, but there is constant danger, and the "pus tubes" may at any time produce a rapidly fatal peritonitis.

The fearful consequences of these diseases, whether produced by gonorrhœal infection or from the introduction in various ways of staphylococci or streptococci, should urge us to consider some mode of protection. No disease is more serious in its possible results. No greater calamity can happen to a woman. It blights forever her dearest hopes, cruelly darkens many of her brightest visions, and destroys forever the organs that make her a woman, and by which she may become a mother. The removal of the diseased uterine appendages by surgery is only to save her from more serious possibilities. With or without the operation she is in danger.

DOES PRESSURE MYELITIS EVER RESULT FROM LATERAL CURVATURE?[1]

By HENRY W. BERG, M.D.,

NEW YORK.

To anyone familiar with the various forms of paraplegia complicating Pott's disease of the vertebræ, the question as to whether similar disturbances of the function of the spinal cord ever complicate lateral curvature ought not to be a new one. In the course of my experience in orthopedic cases, I was constantly on the lookout for cases of paraplegia following lateral curvature, and while, as I shall again state later on, well-marked paraplegia had until recently not come under my notice, milder forms of trophic and motor disturbances complicating lateral curvature had often been seen by me. As to whether the nervous symptoms were the sequence of the lateral curvature was a question which I was disposed to answer in the affirmative, but which orthopedic surgeons with whom I consulted were disposed to consider of independent origin.

It is claimed by the vast majority of our *confrères* that there is no analogy between the angular curvature of Pott's disease and the lateral curvature of scoliosis. The chief difference is that in the former the bodies of the vertebræ are the seat of a degenerative inflammation and the curvature results from the breaking down of diseased vertebral bodies, while in the latter the curvature is the disease, there being primarily no inflammatory process as a cause of the lesion. It is furthermore claimed that the myelitis of Pott's disease is possibly only an extension of the inflammatory process from the vertebræ into the spinal cord. Were this the real pathology of the so-called pressure myelitis of Pott's disease, I must confess that it would prohibit our using the well-known frequency with which Pott's disease is followed by paralysis as a basis for expecting similar paralyses to result from lateral curvature. But the pathology of Pott's disease is not that of an extension of the inflammatory process from the bony tissues to the cord. Indeed the very term pressure myelitis of Pott's disease precludes such an idea. It is not a tuberculous inflammation of the spinal cord; it is not even always a transverse myelitis, but often takes on the clini-

[1] Read before the Orthopedic Section of the New York Academy of Medicine.

cal features and history of inflammation of a chronic character of the cord on a level with the angular curvature, and secondary degeneration in the motor tracts below the level of the deformity. In other cases the posterior columns are affected, as shown by sensory disturbances, while motor symptoms are absent, while in still other cases lancinating pains with trophic and motor disturbances attest the presence of a pachymeningitis with pressure on the spinal nerve roots. Very rarely indeed has paralysis been found due to the pressure of displaced fragments of necrosed bone. It may be permitted me also to call attention to the character of the inflammatory process affecting the cord in Pott's myelitis. It has not been found to be tuberculous in kind, as it should be, were it an extension of the affection in the vertebral bodies, but it is the ordinary chronic inflammation with proliferation of the connective tissue and wasting of the medullary nerve-fibres. The frequency with which recovery from Pott's paraplegia occurs, and this disease has a most remarkable tendency toward recovery, attests the benign character of the inflammation.

If, then, the paralysis of Pott's disease is not as a rule due to a myelitis caused by juxtaposition with an inflamed bony canal, it may rightly be assumed that pressure of some sort is the exciting cause. This pressure, however, as I have already hinted, is not a direct pressure due to deformity of the spinal canal; for even in the most excessive cases of angular curvature the spinal foramen retains an almost normal lumen (Warren Museum specimen in Dr. Gibney's article in "Buck's Handbook of the Medical Sciences"), the disease being limited to the body; the arches of the vertebræ are not disturbed, and the spinal canal remains fully patent. We must rather assume that the long-continued flexion of the cord upon itself is a direct cause of the interference of the circulation in the cord, which finally results in the chronic meningitis and myelitis. In other words, the pressure is an intraspinal cord pressure. In the case of Pott's disease the flexion is sufficiently acute to render myelitis a comparatively frequent complication. In lateral curvature the flexion, a lateral flexion and not an antero-posterior one, as in angular curvature, is not acute, but is gradual. It extends over a larger surface of cord and is, as a rule, sigmoid, and myelitis is a rare complication, the circulation of the cord and its membranes being less interfered with. Furthermore, the deformity of lateral curvature increasing much more gradually than that of Pott's disease, the circulation of the spinal cord has more opportunity to adapt itself to the altered axis of the spinal canal.

I must mention here, however, that one of the arguments *a priori* against the possibility of the occurrence of myelitis due to the lateral flexion which the cord suffers in lateral curvature, is that in normal and healthy people the spinal column is constantly being flexed in every direction without any interference with the function of the cord. But this consideration would not invalidate the possibility of the occurrence of myelitis and other disturbances of the function of the cord in consequence of the permanent, although gradual, lateral flexion which it undergoes in scoliosis. We have other examples in the human body where a transient disturbance of position does not produce disease, while a permanent malposition does; and this too in organs far less sensitive in their structure than the spinal marrow. To borrow an example, for instance, from gynecology, it will be recalled that the uterus, swaying with every movement of the body in health, will, if owing to disease of itself or appendages it suffer a permanent flexion, even to a slight degree, give rise to chronic inflammation and disease of the organ. How much more readily, then, should we expect so friable and delicate an organ as the spinal cord, with its complicated ramification of blood-vessels, to suffer when it becomes the seat of permanent flexion?

Could I, however, offer only theoretical reasons why the spinal cord could occasionally become the seat of disease in scoliosis, this paper would be futile. Where are your cases? would be the natural query. I confess they are not numerous, so rare indeed are they that an extensive search in the literature of the subject has revealed the following conditions:

1. I have found no authority on the pathology of scoliosis who even mentions that the spinal cord has ever been examined in lateral curvature.

2. No authority gives a clinical history of any cases in which disturbances of innervation accompanying lateral curvature are ascribed to pressure on the cord. I have found but two who even in a remote way acknowledge that the cord is ever affected in lateral curvature. Sir Charles Bell supposes that very often paraplegia and other forms of cord disturbances must be often caused by lateral curvature. Dr. Stedman, in his article in "Buck's Handbook of the Medical Sciences," confesses that the condition of the cord in lateral curvature has not been sufficiently studied to enable us to express any opinion as to what lesion or injury it suffers in this form of spinal deformity. Drs. Bradford and Lovett state positively that lateral curvature never gives rise to cord symptoms.

3. I have found the most advanced forms of degeneration in the muscles and ligaments of persons suffering from lateral curvature, particularly when such degeneration, etc., occurs on the convex side of the deformity, accounted for by almost all writers on the theory that they are the result of disuse. Would these writers accept such a pathology for similar muscular disturbances occurring in the limbs of patients not suffering from lateral curvature, or would they look for cord lesions to account for them?

Some years ago, while at the Orthopædic Dispensary, I had occasion to examine, electrically, the muscles of many cases of lateral curvature. The object I had in view at that time, at the suggestion of Dr. Schaffer, was to seek in the condition of the muscles and nerves of the spine for the etiological factor in the production of the scoliosis. My investigations did not reveal any such etiology, but I did find positive proof in several of the advanced cases that the atrophic and degenerated condition of the muscles on the convex, and even on the concave, side of both primary and secondary curvatures, was not the result of disuse or hyper activity, as the case might be, but of organic affection of the trophic and motor centres of the cord. Of course, I do not include among these such cases in which a lesion such as poliomyelitis or hemiplegia was the primary factor and the lateral curvature secondary to the paralysis. But I did find that where, for instance, in a primary dorsal scoliosis, the mammæ were atrophied on the convex side of the deformity, there was also diminished faradic contractility in the pectoral and rib muscles on that side of the chest, and in isolated cases even a reversal of formula with diminished quantity to the galvanic stimulus. In every case there was increased patellar tendon reflex; there was sometimes clonus readily obtained in an extended wrist, and other symptoms of exalted irritability so common in lateral sclerosis of the cord, without any of the spastic conditions so characteristic in this affection.

Hysteria, so common in the very subjects who are most frequently affected by lateral curvature, has had to bear the brunt of all of these symptoms of exalted irritability. But certainly atrophy and degeneration of muscles and organs are not symptomatic of hysteria. Recently, however, I have had under observation in private practice a most remarkable case of lateral curvature which is so interesting that I shall beg the indulgence of the Section while I relate it.

Miss X——, twenty years of age, in perfect health until thirteen years old, when her father noticed for the first time that the right shoulder was higher than the left and the left hip more prominent than the right. He took his daughter to the family physician, who made an examination and found that the patient was suffering from

lateral curvature. The doctor advised a brace of some sort to be worn. The young lady was taken to an instrument-maker, who made a brace for her after consulting with the family doctor. I have been unable to get an accurate description of the apparatus, but it appears to have been some arrangement with perineal straps. This brace the patient wore for a year or so under the occasional observation of the instrument maker. At the end of that time the father finding the lateral curvature of the spine growing worse, and the patient having begun to complain of pain in the right leg, she was taken to another physician, who advised a brace of another character and put her upon tonic treatment. Some months later the friends noticed that the patient was dragging the right leg in walking, while the girl herself complained of stiffness of the right leg with a tendency to trip over the toe. The patient was now sent to a neurologist, who advised massage and the removal of the brace. In spite of this treatment, however, the walk became worse, and she began to have difficulty with the left leg similar to the trouble she had in the right. Both legs were stiff, she walked with effort, and she found it particularly difficult to bring the heel down on the ground. During the time that she was growing worse she consulted many neurologists, but notwithstanding the tendency was always toward aggravation of her symptoms. In the past year she has begun to have trouble in the use of the left hand and arm; she has found she cannot control the movements of her left hand sufficiently to do any delicate work, such as piano-playing. She invariably misses the keys with the left hand, though she reads music well; the right hand also is becoming affected. She has great difficulty in signing her name, although the trouble in the right hand is much less in degree than in the left. Her walk is now extremely bad; she cannot separate her limbs readily; she cannot go up and down stairs without assistance, and requires aid in walking across the room on a level floor. There have never been any bladder or rectal symptoms; she has had no trouble of speech or sight; is not conscious of any disturbance of sensibility; no pain or anæsthesia; eyesight perfectly normal; has had no double vision; has menstruated regularly since the fifteenth year; no history of nervous diseases in the family; mother died of phthisis.

Examination.—Patient intelligent, fairly well built; no sign of atrophy of the limbs or arms; spinal column curved laterally to the left (convex) at the lumbar region; a smaller secondary curve to the right at the upper dorsal region; the curves are accompanied by only slight rotation; the arc of the lower curve measures about one inch and a half at the highest point, no atrophy of the abdominal muscles at either side; the right breast somewhat smaller than the left. So that the patient suffers from a primary lumbar scoliosis, with a compensatory curve in the upper dorsal region.

Nervous Symptoms.—Patellar tendon reflex markedly exaggerated, and marked ankle clonus on both sides; the abductor muscles of the thighs contracted and resisting forcible abduction; walk typically spastic and jerky, more so on the right side than on the left; the heel does not touch the ground in walking, on either side; she can touch a given spot with the point of her great toe only with extreme difficulty; she can walk without aid on the level floor, but is unable to go up and down stairs alone; dynamometer shows good grasp in hands, stronger in the right than in the left; no reflex at the wrist or elbow, no ataxia of either hand; writes name with difficulty, owing chiefly, as she says, to "stiffness" of the fingers; tongue does not deviate to either side when protruded; the muscles of the face act well on both sides, although patient gives a history of having suffered from Bell's palsy when eight years old, from which she recovered entirely; no strabismus; eye-muscles normal; no nystagmus; field of vision normal; no difficulty in deglutition; no stammering; no anæsthesia in limbs or arms, or any part of the body; fundus of the eye shows nothing abnormal; no difficulty of accommodation in vision; patient reads well at ordinary distance; no abnormality in the sense of taste or smell.

Diagnosis.—Lateral curvature of the spine. Three years subsequent, lateral sclerosis of the cord, beginning at the lower dorsal region and passing downward so as to affect the remainder of the cord. Within the past year, a new focus of sclerosis in the lateral columns of the cord higher up, about at the level of the lower cervical and upper dorsal enlargement. This separate focus is necessitated by the fact that sclerosis of the lateral columns or motor tracts of the spinal cord does not progress centripitally, but centrifugally. This is not a case of disseminated sclerosis or *sclerose en plaques*, for the reason that we have clinically no symptoms which would point to sclerotic patches in any other portions of the nervous centres. There are no sensory disturbances, no eye symptoms, no stammering, no difficulty in deglutition, no symptoms except those of derangement of the motor tracts in the lateral columns of the cord. There are no symptoms of interference with the functions of the cortex of the brain or other cerebral centres. No hemiplegia which would point to the internal capsule for its pathogenesis. We have, then, a systematic sclerosis of the lateral columns of the cord, and not a secondary degeneration of these columns due to cerebral disease. I furthermore believe that this sclerosis of the columns of Tuerk in this case is the direct result of the sinuous flexion which the cord has undergone in consequence of the preceding lateral curvature. I have arrived at this conclusion upon the following grounds: 1. A primary systematic sclerosis of the lateral columns is an exceedingly rare disease, and in the opinion of many authorities an impossible affection Where symptoms point to such a disease it is fair to presume that the sclerotic degeneration is secondary to either cerebral abnormality or disease, or to a myelitis of the cord, with a secondary degeneration of the lateral columns below the level of the myelitis. Says Byron Bramwell:[1] "The conditions most likely to be mistaken for primary lateral sclerosis is any lesion which produces slow compression of the cord, and which causes secondary descending degeneration. In making the diagnosis attention must be directed to the condition of the vertebral column." The myelitis in this case, I presume, is due to an interference in the circulation of the cord, owing to its flexion, in accordance with the direction of the deformed spinal canal. This flexion being a lateral one, the greater amount of interference would necessarily be in the lateral portions of the cord. The fact that the right leg was the first to become affected would indicate that the pressure was greatest in the convexity of the curve. Furthermore the occurrence of the affection in the left arm to a greater extent than in the right would be accounted for in a similar manner, the secondary curve being toward the right and convexity to the left.

The object of this clinical contribution is, 1, to call attention to the possibility of a pressure myelitis resulting from lateral curvature. That the condition is rare is most probable, the flexion which the cord undergoes being gradual, and in most cases slight, so that the cord is enabled to adapt itself to its new abnormal position without suffering any pathological alteration. 2. That the atrophy and degeneration of bones and muscles, as well as organs (mammary glands), occurring on either side of the curve, is not due to disuse of these muscles and organs and glands, but to changes in the trophic centres of the cord as a direct result of the lesion which it suffers from the lateral and rotatory displacement of the bony canal in which it is lodged. These latter conditions are not rare, but exceedingly common, and I think that my paper will warrant the conclusion that they are due to an affection of the spinal cord less in degree than the case which I have related. If this case serves to direct the attention of neurologists and orthopædists to the frequency of spinal cord affection in lateral curvature,

[1] Diseases of the Spinal Cord. 1882.

the literature will soon teem with examples of well-marked pressure myelitis complicating lateral curvature.

245 Seventh Street.

Therapeutic Hints.

Treatment of Pruritus Vulvæ.—Dr. J. B. Kessler, of Iowa City, writes: "I noticed in the Medical Record of April 30, 1892, treatment of pruritus vulvæ by galvanism. I have used for many years hydrarg. corrosiv. chloride for the same; also for pruritus ani. I formerly used it in alcoholic solution, but latterly in tincture of myrrh, gr. ij.–iv. to ℥ j. After cleansing the parts thoroughly with hot water, apply with sponge or probe, wrapped with cotton; two to three applications is usually sufficient. I might add that the tincture of myrrh is not original, but read of it several years ago from Prince A. Morrow, M.D., of New York, recommending it as a vehicle in treating tænia circinatus.

Bromidrosis of the Feet.—A powder of alum, 2 parts, in talc, 10 parts, is recommended as of value in sweating of the feet.

Acne.—The following is said to have been very serviceable in acne:

℞. Sulph. præcip. ..... gr. xv.
Spt. camphoræ ..... ♏ v.
Glycerini ..... ℥ ss.
Aq. calcis ..... ℥ j.

Sig.: Apply freely at night, and wash off in the morning.

A 1 to 1,000 solution of corrosive sublimate in emulsion of almond oil is also recommended in this condition.

Locomotor Ataxia.—A modification of the suspension treatment of tabes consists in the forcible flexion of the thighs on the abdomen, the knees being held extended. The manœuvre sometimes causes severe pain, but no other untoward symptom has been reported from its use.

Treatment of Diphtheria in Paris.—The following treatment of diphtheria in children is much advocated at present. The room is steamed with a solution as follows:

Phenic acid ..... ℥ ij.
Salicylic acid ..... ℥ iv.
Benzoic acid ..... ʒiss. jss.
Alcohol ..... ʒiss. iv.

A tablespoonful is put into a quart of boiling water and renewed every three hours.

As a local application:

Camphor ..... ℥ v.
Castor-oil ..... ℥ iv.
Alcohol ..... ℥ iij.
Phenic acid ..... ℥ j.
Tartaric acid ..... ʒi.

—*Medical Press.*

Injection for Gleet.—

℞. Hydrarg. bichlorid ..... gr. ¼.
Zinci sulph. carbolat ..... ℥ ss.
Acid boric ..... ℥ jss.
Liq. hydrogen peroxid ..... f℥ iv.
Aquæ destillat ..... ad f℥ vj.

M Use injection in the morning and evening.

—Dr. A. Hewson, *College and Clinical Record.*

Pruritus Vulvæ.—The wash described below has been found useful by Dr. Bulloch, in cases of pruritus vulvæ:

℞. Aluminii nitras ..... gr. xxiv.
Aquæ ..... ℥ iv.

M. Sig.: Wash the parts once or twice a day, and use as a vaginal injection in the same way.

—*N. E. Medical Monthly.*

Bubo.—Dr. A. Hewson, of Philadelphia, uses an ointment of ichthyol ℥ ss. in lanolin ℥ jss. as an application to bubo.

Treatment of Dysentery.—

Salol ..... ℥ j.
Syrup of tolu ..... ℥ ij.
Extract of opium ..... grs. ij.
Cognac ..... ℥ j.
Gum water ..... ℥ vij.

A tablespoonful every hour.

—*Medical Press.*

Rheumatism.—Dr. Hebbing employs the following as a local application in the treatment of rheumatism:

℞. Salol,
Sulphuric ether ..... āā ℥ j.
Collodion ..... ℥ j.

To be applied around the joints which are affected by acute rheumatism.

—*L'Union Médicale.*

For Enlarged Spleen.—The following prescription I used for ten years in the swamps of Arkansas, and it seldom failed to effect a cure when used a directed:

℞. Quininæ sulph.,
Ferri redacti ..... āā ℥ ij.
Strychninæ sulph.,
Acidi arseniosi ..... āā gr. iij.
Ext. gentian, q. s.

Misc. et fiat pill. No. 70.

Sig.: One pill three times a day.

If the stomach is weak and will not bear more, begin with one pill and increase to three per day. Stop the fevers first for two or three days with quinine before beginning this treatment. Treatment should be continued from one to two months, or until the enlarged gland can be no longer felt. This has served me better than any other remedy in all chronic malarial cases. For children I use soluble citrate of iron, iodide of potassium, and Fowler's solution, in syrup of orange or a suitable elixir.—B. P. Wilson, in the *Medical World.*

Formula for Wine of Coca.—The *Pharmaceutische Post* gives the following formula for making a good coca wine:

℞. Coca-leaves ..... ℥ iij.
Cognac ..... ℥ jss.
Sherry wine ..... Ojss.
Hungarian wine ..... ℥ vj.

Macerate for several days and add seven grains of citric acid. Allow this mixture to stand for several days and then filter.

Phosphorus Poisoning.—A one third per cent. solution of permanganate of potassium is recommended as an antidote in phosphorus poisoning. It is said to convert the substance into phosphoric acid.

Treatment of Pneumonia.—Dr. L. B. Young, writing in the *Times and Register* on the management of pneumonia, says that in the early stage he gives from five to eight drops of tincture of aconite or of veratrum viride every two or three hours (cautiously, we hope), and in the stage of hepatization, to promote absorption, he makes use of the following formula:

℞. Ammonii carbonatis ..... ℥ ij.
Potassii iodidi ..... ℥ jss.
Syr. aurantii cort ..... ℥ ij.
Aquæ ..... ℥ ij.

M. S.: Teaspoonful every two hours.

He also generally blisters. When there is much depression and debility he combines digitalis with the ammonium and potassium mixture. He claims that under this mode of treatment he has never lost a case. If others were equally successful the disease would soon lose its terrors.

Scabies.—

℞. Petrolei ..... ℥ iv.
Ceræ albæ ..... ℥ iv.
Alcoholis ..... ℥ v.
Saponis ..... ℥ x.

M. et ft. unguentum.

—*Nouveaux Remèdes.*

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 43, 45 & 47 East Tenth Street.

New York, May 28, 1892.

TYPHOID FEVER IN BOSTON.

THE recent series of discussions on the modern treatment of typhoid fever before the Practitioners' Society of this city, has been supplemented by Dr. A. L. Mason's careful study of 676 cases of typhoid fever admitted to the Boston City Hospital in 1890 and 1891 (*Boston Medical and Surgical Journal*).

Dr. Mason shows that for purposes of therapeutic comparison, a series of not less than 600 cases must be obtained. Thus the mortality-rate among his 676 cases was 10.4 per cent.; but on one occasion there were 54 consecutive cases without a death, while the mortality-rates among groups of 100 ranged from six per cent. to fourteen per cent.

If this general law were established that one must have 600 cases before he can pretend to generalize therapeutically, it would have a very conservative effect upon the literature of remedies.

Some general clinical facts are given by Dr. Mason regarding his cases. Thus there were 65 under fifteen years of age, 523 between fifteen and thirty-five, and only 88 after the age of thirty-five. The mortality was only three per cent. among children, and was greater after the age of thirty-five.

There were 445 males and 231 females; the mortality was two per cent. higher in the latter.

As regards treatment, there does not seem to have been any systematic attempt to follow up hydrotherapy or antisepsis, or any other special method. Cold sponging, phenacetine, hydro-naphthol, salol, etc., were used in different sets of cases.

The conclusions which he draws are: 1. That in the Boston City Hospital the mortality in typhoid fever from patients admitted moribund and with grave complications is four per cent. 2. That at least three per cent. more die from intestinal perforation and hemorrhage. 3. That little diminution in the mortality from these causes can be expected under any mode of treatment 4. That the mortality from renal, pulmonary, and circulatory disturbances, from diarrhœa and pyrexial exhaustion, is about 3.5 per cent. 5. That, excluding deaths from intestinal perforation and hemorrhage, the mortality among females is 3.4 per cent. greater than among males. 6. That a diminution of two per cent. in the general mortality might be expected from the systematic use of cold baths, the reduction being largely in females. 7. That favorable results followed the trial of intestinal antiseptics, but that relapses were not prevented thereby, and that a much wider experience is necessary to determine their value.

One is struck with the fact of the great amount of typhoid fever in Boston. We doubt if all the hospitals of this city have at any one time as many cases of this disease as the City Hospital of Boston. It looks as if the subject of prophylaxis might profitably engage the attention of the profession of that town.

HEART PAIN.

THE statement is often made to patients who complain of pain about the heart, that it is due to the pressure of the stomach when distended with food or gas. It is unquestionably true that many who think they have heart disease are in reality dyspeptics, but it is equally well known that many conditions produce painful sensations of various kinds in the heart itself, and when intercostal neuralgia, myalgia, or muscular rheumatism of the chest-wall, cutaneous hyperalgesia, and localized pleuritis have been eliminated, there still remains a considerable number of causes for pain in the heart region.

Nothnagel has recently made the attempt to show the causal relation between cardiac pain and actual disease of the organ, and has tabulated nearly five hundred cases of valvular disease with this object in view, excluding neuroses with precordial pain as well as instances of pericarditis. The result of his study of the question, which is published in the *Zeitschrift für Klin Med.*, shows cardialgia to be frequent in cases of insufficiency and stenosis of the aortic orifice, while it is extremely rare in insufficiency of the mitral. Sixty per cent. of regurgitation in the former were found to be accompanied by pain, while only seven and a half of the latter cases had painful sensations. Hyperalgesia of the skin localized over the region of the heart, even in the absence of spontaneous pains, was observed in a number of subjects. Attention is also called to the frequency of pain in disease of the heart muscle, without concomitant valvular implication, as in simple myocarditis, fatty heart, cardiac hypertrophy, etc.; but the cardialgia in these special cases has nothing especially characteristic about it, and is only frequent in instances of arterio-sclerosis with hypertrophy. The obscurity which involves the whole subject of the heart's nervous system prevents the author from entering upon a discussion of the pathology of these various pains, but he regards them as of much importance in the diagnosis of obscure cases.

Dr. Liégeois has recently reported to the Société de Thérapeutique several observations on the effect of the tincture of piscidia erythrina in certain heart-pains, and has been led by his own experience with the drug to regard it as a good analgesic in the more or less permanent pains of vascular cardiopathies. The effect of the remedy is said to be more analgesic than hypnotic, and it produces no gastric disturbances. It is said that its active principle, piscidine, slows the heart's action and lowers the arterial pressure. It is very necessary to have a tincture prepared properly and not too long beforehand, as it does not keep well.

The formula which the writer especially recommends is as follows :

℞. Tinct. piscidæ erythrinæ..... gm. 60.
Tinct. verat. virid.,
Ext. aconiti rad. alc. ..... āā. gm. 15.
S.: 30 drops morning and night."

It is greatly to be hoped that piscidia may prove a more valuable remedy for the relief of pain about the heart than many others which have been recommended for this purpose. Some of these painful sensations are very distressing to the patient's mind as well as physically, and are not usually relieved by the remedies which act beneficially upon the action of the organ.

DISASTROUS RESULTS OF SYPHILIS.

Within the past few years many important and substantial contributions have been made to our knowledge of the disastrous results that follow the inroads of syphilis in the nervous system ; but it is rarely that we have the subject so vividly portrayed with its sad and terrible consequences as has been recently done by M. Morel La vallée in a late number of the *Gazette des Hôpitaux*. He recites the case of an eighteen-year-old female who contracted syphilis a short time before, and then transmitted it to her lover, a medical student. His infection was followed by headache with increasing severity, irritability of temper, marasmus, and death in about two months from syphilitic meningitis.

The following year the same young woman, having become the mistress of a second medical student, who is dubbed Secundus by the author, likewise infected him with syphilis. She then quitted Secundus for Tertius, with whom she lived maritally for some time, and during this period she was twice confined. After nine years Tertius entered the matrimonial state, and in due time his wife was likewise delivered of two children, healthy and robust. Some years afterward he became delirious, tried to kill his children, of whom he had previously been very fond, and it was soon necessary to confine him in an asylum. Diagnosis, general paralysis resulting from ancient syphilitic infection. His death followed shortly afterward. A similar fate was meted out to Secundus, after a very similar marital experience.

Quartus, the next victim in order, it is pleasing to remark, was not a medical man, but allied to him, a pharmacist ; he came, however, to the same sad end, to wit, death from progressive general paralysis, maniacal in form. Monsieur le Quintus, an engineer, also found his death from syphilitic insanity.

It is a sad commentary on the dealing out of just deserts, to know that the source of all this evil is legitimately married, in excellent health, and her children in good condition.

We have in mind a very similar case to the one in question, in all respects except the unfortunate results, which have not as yet, however, had time to develop. Two brothers worshipping at the same shrine of Venus were infected with syphilis, and they in turn were followed by a third, who carried away a like result. How many more were dealt with after the same generous fashion it is impossible to say ; they may have been legion, for the foul source of this iniquity was still held out to Mammon, even after the mercenary Cyprian under whose roof these pleasures, which are followed by death, were for sale, was requested to withdraw her and send her to a hospital for treatment. This is a shining example of one of the results of illegal and uninspected prostitution.

The above-quoted gentleman also gives a genealogical table of the disastrous results of syphilis as follows : M——, an aristocrat, a high liver, and given to excesses of all kinds, marries Z——, very religious, very intelligent.

THREE CHILDREN.

The Eldest :	*The Sister :*	*Son, the Youngest :*
Nervous tic of the face ; pusillanimous ; can hardly learn to read and write ; tremor ; incapable of managing his own affairs ; taciturn and suspicious ; diagnosis ; "dementia partialis."	Lively, epileptic, in intellect an imbecile ; was born with (? an atrophy of the arm.	Full of life ; plays ; very intelligent ; very irascible ; has killed on a voyage a man on board ; afterward, at twenty-eight years of age had syphilis ; died at thirty-eight years of age after having presented the following symptoms : alternating delirious ambition with terrific hallucinations, he wished to sell Austria and India ; everything was in diamonds or gold ; incoherence ; difficulty in speech ; unconsciousness. Diagnosis, "general paralysis."

THE DOCTOR AND GOOD ROADS.

The sentiment in favor of improving country roads is growing every year. It has reached our legislative assemblies, and bills are being introduced in order to secure State aid in the matter. Good roads are things which no class of persons would appreciate more than physicians, and to none would they bring more direct personal comfort, and even practical financial help. On a good road the country doctor can travel ten miles an hour, on a bad one barely five. The time required in doing his work is doubled, the physical weariness is increased, the amount of visiting rendered possible is curtailed. Besides this, the patient suffers, for the doctor's visits are delayed and less numerous. He cannot watch the patient so closely, and he brings to his work a wearied body.

Perhaps the horse would argue most eloquently of all, if he could speak, in favor of good roads. His working life would be lengthened and his working days made easier.

With good roads the bicycle could be utilized, and through its invigorating influence, perhaps, the country doctor would cease, as years rolled on, to become obese from too much sitting in a wagon, his wits would be sharper, his professional work better.

By all means, then, let the doctors take up the gospel of good roads and urge forward their construction. They make intercourse more easy, work less burdensome, life more enjoyable ; and they are in fine an index of the progressiveness and civilization of a community.

News of the Week.

The Mississippi Valley Medical Association will hold its eighteenth annual session at Cincinnati, Wednesday, Thursday, and Friday, October 12, 13, and 14, 1892.

The American Academy of Medicine.—The seventeenth annual meeting of the Academy will be held at the Hotel Cadillac, Detroit, Mich., beginning on Saturday, June 4, 1892.

Dr. Elbridge G. Seymour, of Hermon, N. Y., died of cerebral hemorrhage, at the St. Lawrence State Hospital, May 4, 1892, at the age of fifty-six years. Dr. Seymour was graduated at the College of Physicians and Surgeons, New York, in 1860, and located in practice at Redwood, N. Y. At the organization of the Ninety-fourth Regiment N. Y. Volunteers, he became Assistant Surgeon, and, later, Surgeon of the regiment, serving to the close of the war. Upon returning home he located in Hermon, where he has since resided, practising his profession and engaging in business.

Anniversary Dinner of Hospital Graduates' Club.—The seventh anniversary dinner of the Hospital Graduates' Club, of New York, was held at the New York Academy of Medicine, Thursday evening, May 19th. Dr. N. H. Henry, the President of the club, after some appropriate remarks upon the growth and prosperity of the organization, acted as toast-master. Speeches were made by the following guests: Drs. George F. Shrady, L. B. Banks, George B. Fowler, D. B. Delavan, Frank P. Foster, and W. K. Simpson; and also by the following members: J. E. Newcomb, John Ridlon, F. A. Manning, C. A. Powers, R. W. Amidon, and H. Locke.

Philadelphia Polyclinic.—At the last meeting of the Board of Trustees of the Philadelphia Polyclinic and College for Graduates in Medicine, an additional Chair of Orthopedics was created, and Dr. Benjamin Lee was elected Professor of Orthopedics.

The Epilepsy Bacillus.—The cable announces that Dr. Gerdes, First Assistant in the Pathological Institute of Halle University, announces that he has discovered vast numbers of specific bacilli in the liver, kidneys, and blood of persons who have died of epilepsy. He has experimented with the bacilli on mice and rats, and has found it to have invariably deadly effect.

A Correction.—In the description of a new electrode, etc., in the issue of the MEDICAL RECORD for May 14th, the references were incorrect. Fig. 3 represents the ordinary electrodes in use, while Fig. 2 represents the application of the new electrode with the neutral point thrown outside the body.

Dr. Charles A. Powers has been appointed one of the Visiting Surgeons to the New York Cancer Hospital, Eighth Avenue and 106th Street.

Dr. Frank Hartley has been appointed a surgeon to the New York Hospital, to succeed Dr. Thomas M. Markoe, who recently resigned after forty years' service.

Decision in Favor of a Quack.—The Virginia courts have decided, in the case of a notorious quack, that as he has no residence in the State, he is not compelled to obtain a certificate for registration from the State Examining Board. This renders the law ridiculous, as it subjects the physician who desires to practise regularly to a regulation from which the travelling quack is relieved.—*Times and Register.*

The Vegetarian's Heart vs. the Meat-Eater's Heart.—In the *Nineteenth Century* for April, 1892, Lady Paget, writing on the subject of vegetarianism, and in its defence, gives the following among several arguments: "While the meat-eater's heart has seventy-two beats in the minute, the vegetarian has only fifty eight, therefore twenty thousand beats less in the twenty-four hours."

American Surgical Association.—This Association will meet in Boston, Mass., Tuesday morning, May 31, and June 1 and 2, 1892, in the hall of the Natural History Society on Berkeley Street.

Bequests to Hospitals.—The late William Astor left to the Woman's Hospital of New York, $10,000; to the Home for Incurables, $10,000; to St. Luke's Hospital, at Jacksonville, Fla., $15,000.

A Medical Organization for Social Purposes.—It is proposed to establish a club for social purposes, restricted in its membership to members in good standing in the *Regular Profession* of Medicine in Philadelphia. A modest club-house is to be secured in a central location, to be fitted up with chess-tables, billiard-tables, etc., where meetings can be held, committees have accommodations, and members may congregate for social intercourse. A reading-room is to be opened where may be kept on file the principal medical journals, the literary magazines, and journals of the day. It is contemplated to have occasional (monthly or bi-monthly) dinners, to which non-members of eminence may be invited. The fees and dues are to be moderate, ten dollars initiation at present, and annual dues of ten dollars.

The Man with a Musical Anus.—Some four or five years ago M. Verneuil exhibited to his class in Paris a case of what he facetiously denominated "musical anus." The patient was able at times, when sufficient flatus had accumulated in his colon, to evacuate it with some force, thereby producing a high-pitched musical note resembling that of a violin. On close examination he was found to have, in the cellular tissue about the lower end of the rectum, a pneumatocele, with an opening into it from the rectum, formed by a narrow slit between two thin folds of mucous membrane, which, acting like a reed, produced the sound when the air was expelled from the tumor by forcible pressure from above. Numerous cases of fistula and other deformities of the anus have been seen in which the expulsion of gas from the bowel was accompanied by peculiar sounds, some, perhaps, musical to the enthusiastic observers. But in all these cases there has been some deformity or malformation of the rectum or anus.

Dr. Baudouin, however, has lately reported, in the *Semaine médicale*, a case that may with justice be called one of musical anus, and one that is of much interest from a physiological point of view. The patient, or rather the exhibitor, is a man, aged thirty, well developed, but without muscular excesses, tall, of full weight, and, so far as can be made out, entirely free from any disease or deformity. His digestion is good, and he does not develop

an unusual quantity of gas in the bowel after eating. There is no pyrosis or abdominal tympanites. His fecal passages are normal, regular, and well moulded. The anus and rectum, in a state of repose, present nothing abnormal. The sphincter is moderately strong, but quite distensible, notwithstanding its daily exercise. The rectum is normal and not dilated. The remarkable feature of the case is that the lower bowel, at least, seems to be absolutely under the control of the man's will. He can empty it completely whenever he desires, a very fortunate accom plishment for his clothing and for the olfactories of his audiences. He was reared on the shores of the Mediterranean, and it was here that he first noticed his remarkable power. While bathing one day he observed, upon strong inspiration, the sensation of cold in his pelvis and abdomen, and at the same time felt the sea-water entering his rectum. In a short time he was compelled to empty his bowel, and noticed that he had taken in a much larger quantity than he had supposed. By practice in the ordinary bath and in the sea, he became able to store a considerable quantity of water, to retain it for some time, and to eject it with much greater force than at first. Later on he noticed that he could accumulate air in his bowel, as well as water, and by its expulsion could give rise to certain variations of sound. Applauded by his associates, who acknowledged his superiority in this class of exercise, he eventually developed the faculty beyond measure, and frequently gave exhibitions of his art before a select circle of his friends. From these reunions he began to exhibit his powers in the clubs and cafés, until he became the best known and greatest curiosity of the place. As his reputation spread he made journeys to the surroundings towns and villages, Béziers, Nimes, Toulouse, and Bordeaux. At the latter place he was examined by many of the medical faculty, and it was found that he really could imitate certain musical instruments and emit certain popular melodies.—*New York Medical Journal.*

Obituary.

JOHN F. HAMILTON, M.D.,

SALT LAKE CITY, UTAH.

Dr. John F. Hamilton was born in Litchfield, Conn., December 22, 1830; he died at his home in Salt Lake City, April 9, 1892.

A graduate of Rush Medical College in 1854, his professional work covered a period of nearly two score years—a period crowded with activity and incident, on the frontier and in the Mormon capital, beyond the experience of most professional men. Born a New Englander, he became a thorough man of the West; but east or west, in whatever sphere of life, he would have become a leader.

He began the practice of his profession in Chicago, where his talent and attainments won the esteem of Professor Brainerd, then eminent among Western surgeons, who invited Dr. Hamilton to share his work in the Marine Hospital and private practice. At this time among his intimates were Byferd, Frae, Herrick, Edmund Andrews (his bosom friend), A. J. Johnson, and others since distinguished in the profession, of whom Dr. Andrews alone survives. With such a professional career as he desired thus opening to his ambition, his health unfortunately failed, and he was obliged to leave Chicago, and for a time abandon active work.

In 1856 he married Fidelia Belcher, daughter of an early and prominent citizen of McHenry County, Ill.

In 1860 Dr. and Mrs. Hamilton crossed the plains by wagon to the young city of Denver. The first hospital of Denver, on the site now occupied by the Windsor Hotel, was established by him during his first year's residence. At the outbreak of the war he became surgeon of the First Colorado Regiment, and subsequently medical director of the Army of the Plains.

In 1866 he removed to Salt Lake City, having been assigned to duty as Post Surgeon at Fort Douglas. In 1871, after his resignation from the army, St. Mark's Hospital for miners was established through his efforts, and continued under his charge until his death. Here he did memorable work, both in surgery and in the study of the various phases of lead-poisoning, so common among miners in this region.

His reputation throughout the inter-mountain region was deservedly great, and his field of practice extended from the Rockies to the Sierras.

In person tall and graceful, his countenance and manner expressive of kindliness, courtesy, and manly self-respect; in character bold, self-reliant, prompt and clear in judgment, with magnanimous scorn of everything base or petty, and generous to a fault; these qualities combined to give him a personal power or "magnetism" felt and acknowledged by all who knew him; and in his patients inspired boundless confidence. In the profession, while his writings were scattered and fragmentary, his counsel and aid were freely available to his medical brethren, and his judgment, whether in medical or surgical cases, was rarely at fault. He was particularly generous and helpful to younger practitioners, many of whom hold his timely words of encouragement in grateful remembrance. He assisted in organizing, and was the first president of, the Salt Lake Medical Society, then the only medical society in Utah, whose charter was amended for the purpose of honoring him by re-election to that office. He idealized his profession, and held it ir the highest honor.

His ethical code was summed up in the principle—*noblesse oblige!*

PLINY EARLE, M.D.,

NORTHAMPTON, MASS.

Dr. Pliny Earle, who was superintendent of the State Hospital for the Insane in Northamptom, Mass., from 1864 to 1885, died there on May 18th, aged eighty two. He was at one time medical superintendent of the Bloomingdale Asylum, New York, and visiting physician of the New York City Lunatic Asylum, Blackwell's Island. Dr. Earle had a wide reputation for treatment of insanity, and made several trips to Europe and visited more than one hundred and fifty hospitals there and in America. He was called as an expert to examine Guiteau, the assassin of President Garfield.

Dr. Earle was identified with the attempts to treat the insane by humane and rational methods. His studies upon the curability of insanity were also scientific and valuable contributions, which did much to clear up the question of the efficacy of therapeutics as applied to the insane.

Dr. Earle is said to have been the first person who ever addressed an admittedly insane audience upon any subject that was not wholly religious in character, and his institution of lectures, combining instruction and amusement as a remedial agency, was regarded as a most beneficial innovation.

Doctors of Pharmacy.—The University of Munich has created a new degree—Doctor of Pharmacy—which will be granted after a course of seven semesters and examination in one principal subject, chemistry or botany, and in three secondary subjects, namely: mineralogy, physics, and zoology. An inaugural dissertation must also be presented

Society Reports.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, March 28, 1892.

GEORGE HENRY FOX, M.D., PRESIDENT, IN THE CHAIR.

Discussion on Questions Pertaining to Syphilis.—The questions discussed were: 1. Is it possible to favorably influence the course of syphilis by treatment during its primary stage? 2. What factors influence the severity of the disease? 3. What effect does syphilis exert upon the duration of life?

Is it Possible to Favorably Influence the Course of Syphilis During Its Primary Stage?—DR. J. A. FORDYCE read a brief paper on this subject. The question was obscured to some extent by the fact that the primary stage, with or without treatment, varied in severity in different cases, the full cause of which we did not know. It might be stated at the outset that we had every reason to believe that syphilis was of bacterial origin. He had observed in a number of instances that the early eruptions were severe when they followed an unusually large or œdematous initial lesion, and he had been led to believe that the amount of the virus in the initial lesion had much to do with the early manifestations of the disease. The extremes of youth and old age, and conditions impairing the general health, predisposed to a severe form of the disease. Syphilis not infrequently developed tuberculosis or rendered latent tuberculosis active. Alcohol hastened the evolution of syphilis. Chance alone seemed in the great majority of cases to govern the location of the lesions, whether in the bones, nervous system, etc., while in other cases the weaker parts seemed to be selected. If locomotor ataxia could be attributed to syphilis, this manifestation of the disease selected males for its victims. A number of syphilographers had explained the malignant cases of syphilis on the assumption that the seed was sown in new soil.

DR E. B. BRONSON also spoke upon the first question, Could we influence the course of syphilis by treatment during the primary stage? He said he had not been able to satisfy himself on this point. He would consider the question of treatment during the primary stage under two heads: 1, Preparatory treatment; 2, anti-syphilitic treatment. The former, preparatory treatment, was desirable in order to get the patient ready for the manifestations of the disease. There should be hygienic surroundings, the general health should be improved, one should look to the action of the emunctories—the skin particularly, for upon these the elimination of the poison depended. Attention should be given the teeth and mouth preparatory to the use of mercury.

Regarding the second question, he assumed that syphilis was primarily a local disease: could we, then, eradicate it by excision, etc.? He thought that with the evidence before us at present we must reply in the negative. He was speaking of the poison when it had affected the nearest lymphatics, not of immediate contact. But it seemed to him not at all improbable that by the introduction of mercury within the lymphatic district which corresponded to the region occupied by the chancre we could to a certain extent forestall the effects of the poison. He believed the poison entered by way of the lymphatics. The method which he suggested was by inunctions. He had formerly mentioned hypodermic injections, but his experience had taught him that this was not feasible. If the objections which had been offered by some to the use of mercury during the primary stage had any foundation, he thought they would not apply so forcibly to the local inunctions used as just recommended, the object of which was to attack the poison at its entrance to the system.

Objects to Treatment During the Primary Stage.—DR. EUGENE FULLER stated some objections to anti-syphilitic treatment during the primary stage, relating some experience in support of his objections. The two principal objections were that early treatment obscured the diagnosis, and that the patient would seldom persist with treatment unless the existence of the disease had been fully demonstrated. To show that even the best syphilographers might fail in diagnosis, he referred to two cases in which a lesion was pronounced by experts to be the initial lesion of syphilis, no treatment was instituted, there were no secondary manifestations, proving that there had not been syphilis. He could also relate a number of cases in which the regular course of the disease had been so interfered with by treatment during the primary stage, that afterward there was doubt as to the diagnosis, until paralytic symptoms appeared—symptoms which probably would have been avoided by persistent treatment.

Advises Early Treatment.—DR. W. K. OTIS thought the question of obscuring the diagnosis should have nothing to do with the treatment. As soon as one had made the diagnosis it was his duty to begin treatment by mercury. We knew that the initial lesion or other sore which might ordinarily prove rebellious would heal quickly under constitutional treatment by mercury. He believed secondary symptoms were largely prevented by immediate treatment. This was desirable, for few persons cared to lose their hair, eyebrows, and have disfiguring eruptions, and perhaps be kept home from their business, simply that the physician might be more assured of his diagnosis. As to aborting syphilis, he did not think it possible by any treatment in vogue, yet he would remove an initial lesion as a source of inflammation and discomfort to the patient.

DR. FULLER interjected that he thought Dr. Otis had put the case in an extreme light, for it was not necessary to wait until the eyebrows fell out, and other marked disfigurements occurred before one could be assured of the diagnosis, and thereupon could commence treatment.

What Factors Influence the Severity of Syphilis?—DR. S. ALEXANDER directed his remarks to this question. He would make two subdivisions of it: 1. What were the factors which favorably influenced the course of syphilis? 2. What were the factors which increased its severity? Regarding acquired syphilis, he thought it was more severe in childhood than in old age. Many of the statistics on this subject, and on others also, were misleading. His own experience had not been large enough, of course, to base upon it a positive answer to any of the questions under consideration. It was generally recognized that syphilis was milder in countries where it had existed longest. Idiosyncrasy had to do with the severity of the disease, as it had in small-pox, etc. The discussion on the influence of the rheumatic and gouty diathesis had been a warm one, some holding that they created a tendency to suppurative lesions, others the contrary. His own experience had been that in the rheumatic, the symptoms of syphilis had been mild, yet they had lasted long. Syphilis was worse under bad hygienic surroundings. As to tobacco, its influence was bad only because of the local irritation which it caused in the mouth. The mouth should be put in a healthy state, there should be no sharp broken teeth. As to alcohol, he advised hard drinkers to give it up because of the injurious effects on the general health, and lighter drinkers because of the irritation of the throat. Yet the moderate use of stimulants at the table by those accustomed to it need not be prohibited.

Irregular treatment, which was especially apt to be observed among patients who went from physician to physician, was bad. The symptoms were apt to be aggravated by measures which injured the general health. He also believed that the administration of large doses of iodide of potassium when it was not needed made syphilis severe. One of the greatest evils in New York was indiscriminate "mixed" treatment.

What Effect Does Syphilis Exert upon the Duration of Life?—DR. OSCAR H. ROGERS discussed this subject with

life insurance statistics as a basis. Out of three or four hundred thousand lives insured which he had been enabled to study, there had been fourteen to fifteen hundred syphilitics who had been cured from four to five years. It would require about ten thousand cases as a basis for conclusions which could be regarded as at all reliable. Out of the fourteen to fifteen hundred the mortality had been thirty-seven, which was rather high. The age at death of insured people for a considerable number was about forty-eight, whereas for these syphilitics it had been about forty-one. In other words, syphilitics had apparently lost about seven years of their life by the fact that they had syphilis although they had been "cured" for five years, at the age of thirty the probable length of their lives being, instead of sixty-five, fifty-eight; in other words, a loss of one-fifth of their longevity. The man of fifty years had lost one-third of his longevity, the probability being that he would live only to sixty-four instead of to seventy-one. Roughly speaking, the syphilitic had probably lost from one-third to one-fourth of his longevity.

Among the 17,000 deaths which he had studied among all classes of insured, he had found that 1 in 170 had died of paresis: whereas, among the syphilitic deaths, paresis was the cause in 1 out of 18. He had found nothing to show that syphilitics were more likely to be carried off by lung disease He hoped other physicians would add to these statistics.

Dr. Rogers thought the mortality from syphilis was greatest in continental Europe, then in England, then in the colonies, lastly in the United States. This was, he supposed, to be accounted for, either by the fact that syphilis was milder here, or else we knew better how to treat it.

Dr. Paul Gibier thought it likely the life insurance companies carried many more syphilitics than they supposed, for men did not always consider it obligatory to give a correct answer to interrogatories bearing on this subject. As syphilis was treated to-day, he thought it did not shorten the duration of life. The disease was more severe in new blood.

Be Sure of Your Diagnosis Before Instituting Treatment.—Dr. P. A. Morrow thought it was generally admitted that under constitutional treatment during the first stage the initial lesion melted away faster, and the secondary lesions were deferred; there was, in other words, derangement in the natural order of the symptoms. Yet mercury used at this stage did not modify the intensity nor the duration of syphilis. A positive diagnosis could not be made at the primary stage, yet it was of very great importance to clear up any doubt, and for these reasons he objected to the use of mercury early. Special circumstances might justify using it during the primary stage. Regarding factors which aggravated the severity of syphilis, a number had been mentioned by Dr. Fordyce and by Dr. Alexander. Anything which diminished the constitutional powers had that effect. This was especially striking in charity practice. Injudicious treatment also aggravated the disease. If through idiosyncrasy a patient could not take mercury without poisonous effects, the use of the drug should be discontinued, and other measures be substituted. The same was true of iodide of potassium. There was no doubt but what a good deal of harm had been done by the excessive use of the iodide. The idea of attempting to expel syphilis by therapeutic violence should have no place in the rational therapeutics of to-day. But the most essential factor in aggravated syphilis was the peculiarity of the soil.

Treat Syphilis Early.—Dr. C. W. Allen had held for some years that syphilis should be treated early—as early as the diagnosis was made. He performed excision of the initial lesion, hoping to modify the severity of the disease thereby. It was better to tell a man early that he had syphilis, than to wait for symptoms on which to base a positive diagnosis, allowing him meanwhile to go and infect others. The earlier the treatment of syphilis was instituted the more benign would be its course.

Dr. Gibier said regarding the supposed value of mercury when the drug was administered early, that he had seen some very severe cases of syphilis in persons who worked in factories, where mercury was employed, and whose systems were supposed to be fully under its influence. He thought that in the beginning tonic treatment was better than mercurial.

The Medical Examiners Bill.—Resolutions were passed, opposing legislation to exempt graduates of 1893 from the necessity for appearing before the State Board of Medical Examiners.

INDIANA STATE MEDICAL SOCIETY.

Forty-third Annual Meeting, held in the Plymouth Church. Indianapolis, May 12 and 13, 1892.

Edwin Walker, M.D., of Evansville, President; E. S. Elder, M.D., Secretary.

The members of the Society and visiting physicians were handsomely entertained at the laboratories of Eli Lilly & Co. by the pharmacists. The Pharmaceutical Society was holding its meeting at the same time in Indianapolis.

Dr. Joseph Matthews, of Louisville, Dr. E. S. McKee, of Cincinnati, and Dr. R. B. Hall, of Cincinnati, were among the visiting physicians present.

Prognosis and Treatment of Asthma.—The first paper read was by Dr. Seaton Norman, of Evansville, on this subject. He recommended the removal of patients to the mountains or seashore. Colorado he pronounced the best place in the country for asthmatic patients. For those who cannot change location he recommended cocaine. In some cases, brandy affords relief. In the discussion which followed, cocaine was strongly condemned. Asthma was pronounced the result of a reflex action, the real seat of trouble being in the nose, while it seems to be located in the lungs or bronchial region.

Rare Cases of Malarial Intoxication.—Dr. H. O. Pantzer, of Indianapolis, read the above paper. The rare cases and abnormal conditions diagnosed in this paper were of great interest, and the discussion brought out the result of microscopical investigation of the cause and germs of malaria.

Dr. James F. Hibbard, of Richmond, discussed "Inflammation—Past and Present," which was a well-considered paper, followed by much discussion.

"Etiology of Diphtheria," by Dr. A. L. Wilson, of Indianapolis, was read by Dr Potter, because Dr. Wilson had taken the diphtheria from the study of its germs in the preparation of his paper, and was under treatment at the City Hospital.

The President's Address.—The President, Dr. Edwin Walker, called attention to a number of facts associated with the forty-three years' existence of the Society. Among others that it had accumulated no property of value in that length of time besides its "Transactions." He strongly recommended the establishment of a library. A small sum from each member would do this, and thus the history of medicine from the organization of the Society could be had without difficulty. Doctors could donate rare books, and before long a member would bequeath his library to the Society rather than have it auctioned off for a mere pittance after his death. Such a library would have to be established at Indianapolis, the home and meeting-place of the State Society, but all members are within a few hours' ride of this city, and for a small fee a librarian or some competent person could give an abstract of all articles on a particular subject, as is done in the Surgeon-General's office at Washington.

In this connection he offered another thought. The Society could fit up a bacteriological and pathological laboratory, and employ some competent men to make such examinations as are often necessary for a correct diagnosis. Busy practitioners are usually not prepared, nor have they necessary practice and skill to make such

investigations, and competent men for a reasonable fee could make such investigations as would make us more thorough in our work and better doctors. Let us work together to encourage the talents we have, and build up a complete profession in our State of which not only we, but our colleagues of the whole world, will be proud.

Prescriptions and Prescription-writing. — Following the address of the President came an address by PROFESSOR JOSEPH P. REMINGTON, of Philadelphia, on this subject. A part of the lecture was illustrated, examples of prescription-writing being thrown by a calcium light upon a screen. These showed some of the labors of the druggist in saving the populace from errors and mistakes. He said, in another year the new Pharmacopœia will be published. This is a law book of the land, and it is only through the co-operation of the physician and pharmacist, and through their arduous labors, that a thoroughly representative work can be secured.

Speaking of prescriptions, he said: What marvellous possibilities are bound up in that apparently insignificant scrap of paper covered with the mystical characters, which may, on the one hand, bring hope and happiness to those waiting at the bedside of the loved one, or which, if improperly interpreted or ignorantly compounded, fill the faithful watcher with grief and horror by inviting an onslaught from the grim monster. The medical profession are more deeply interested in pharmaceutical education than are pharmacists themselves. Upon the correct and intelligent rendering of their prescriptions rests the reputation, success, and honor of the prescriber. Pharmacy must be practised by educated, honest, faithful men, alive to the needs of the profession. The educated pharmacist is not the superior of the physician, neither is he his inferior, but he is his peer, and side by side they toil in their noble life work.

A strong beginning was made at the meeting of the American Medical Association last year at Washington toward the founding of a section of materia medica and pharmacy in that body. The position of the pharmacists as fellow-workers was thoroughly recognized by the physicians, and they were cordially welcomed. The second meeting of the section will be held in connection with the Association at Detroit next month.

Bacteriological Investigation.—DR. THEODORE POTTER, of Indianapolis, reported on the progress made in bacteriological investigation. He said that enough had been established to warrant the conclusion that the phenomena following infection are chiefly, if not wholly, due to the action of new products formed in the growth and multiplication of the bacteria.

Preternatural Sleep.—DR. N. N. SHIPMAN, of Seymour, read a paper on this subject, and reported the case of a boy, aged thirteen, whom he had attended, who slept for a month the first time. After that he had long periods of sleep, and on February 11, 1892, went to sleep for eighty-eight hours. He seemed all right for a day after this, then fell asleep for twenty-four hours. Since then he has been a normal boy, apparently well and hearty.

Xeroderma Pigmentosum.—DR. A. W. BRAYTON, of Indianapolis, presented a description of a case of xeroderma pigmentosum, otherwise known as Kaposi's disease, of which but sixty-seven cases have been known, and but three of these in the United States. The doctor has two of these cases in the same family, one a child aged eleven months, the other a girl aged sixteen. The latter was exhibited last summer at the Association of American Pathologists at Washington, and was pronounced the most typical case of the disease yet presented.

Other papers were presented on the following subjects: "The Purpose of Drugs," by Dr. C. S. Bond, of Richmond; "Tenotomy of the Recti Muscles," by Dr. J. O. Stillson, of Indianapolis; "Sympathetic Inflammation," by Dr. George F. Keiper, of Lafayette; "Emergency Laparotomies," by Dr. G. R. Green, of Muncie, and several others.

Election of Officers.—The officers for the coming year are: *President*, Dr. George F. Beasley, of Lafayette; *Vice-President*, Dr. C. H. Smith, of Lebanon; *Secretary*, Dr. E. S. Elder, of Indianapolis; *Assistant Secretary*, Dr. N. N. Shipman, of Seymour; *Treasurer*, Dr. J. O. Stillson of Indianapolis. Standing Committees on Ethics, Publication, Arrangements, Bacteriology, Necrology, and Progress in Medicine and Surgery, were appointed by the President-elect.

The efficient Chairman of the Committee of Arrangements, Dr. F. C. Woodburn, was presented with an elegant operating-chair by the medical exhibitors. He was appointed Chairman for the ensuing year.

Correspondence.

THE HEALTH RESORTS ON THE RIVIERA.

(Continued from p. 500.)

VI.—ST. RAPHAËL, FRÉJUS, GRASSE, JUAN-LES-PINS, CAP D'ANTIBES, BEAULIEU.

(From our Special Commissioner.)

ST. RAPHAËL—HISTORICAL REMINISCENCES—PRESENT CONDITION—A FINE BEACH—A REVIVAL PREDICTED—BAD DRAINAGE—THE DRINKING WATER—A NEW MEDICAL ESTABLISHMENT. FRÉJUS. GRASSE: SITUATION—PERFUMERY—THE CLIMATE—PROTECTION FROM WINDS—SANITARY AFFAIRS—THE DRINKING-WATER—ANALYSIS OF GRASSE DRINKING WATER—THE GRAND HOTEL—INDICATIONS. JUAN-LES PINS: QUITE A NEW PLACE—EXTENSIVE PINE FORESTS—SANITATION AND WATER-SUPPLY. CAP D'ANTIBES. BEAULIEU: A SHELTERED NOOK—SOME WELL-KNOWN RESIDENTS—THE DRINKING-WATER—DRAINAGE—CLIMATE—PICTURESQUE SITUATION.

BEAULIEU, March, 1892.

THE present letter will be devoted to a number of winter stations which are less generally known than Nice and Cannes, but which nevertheless have certain pretensions to be regarded as Riviera health resorts. They are all smaller, and also much less expensive to live in, than fashionable Cannes, gay Nice, or quiet Hyères and Costebelle. But the hotel and villa accommodation is also more limited, and, in a general way, it must be admitted that house-keeping there is rendered more troublesome and less satisfactory.

St. Raphaël.—To properly appreciate this village or "town," if the local appellation may be borrowed, it is necessary to indulge in some looking backward. Every school-boy knows, or at least ought to know, that Napoleon landed at St. Raphaël in 1799, on returning from Egypt. In 1814 the same gentleman, under somewhat altered circumstances, embarked there for Elba. Plain Americans, however, whether returning from Egypt or not, usually try to crowd their embarking from St. Raphaël into the same day that witnessed their landing.

Not that the village, with its 4,000 inhabitants, is not prettily situated on an attractive bay; not that the air is not pure there, and at times heavily scented with the pungent perfume of the extensive pine-forests near it; not that there are no fine views and charming walks to be enjoyed in its immediate neighborhood. But because St. Raphaël strikes the average visitor as such a mournful, shabby-genteel, half-deserted, very much over-built sort of a place. It has evidently seen better days. But after a short-lived boom, when many glorious bubble visions were indulged in, the dandified little village has now apparently settled down to share, with near by Fréjus, the reputation of once having been something. Yes, it must be owned, St. Raphaël is decidedly disappointing.

Nevertheless, its sandy beach has a very tempting look about it, and in summer time it is put to good use by

plenty of native bathers. During the winter season natives never bathe, as it has been found to interfere with the successful exhalation of waves of garlic. But an occasional hardy Britisher may be seen to enjoy chilly punishment there, by taking a daily dip throughout the midwinter months.

It takes about forty minutes by rail to get from Cannes westward to St. Raphaël. And it would seem to take most people less time than that to get away again.

But the spirit of the St. Raphaëlites has not yet been broken. They are busy again just now in talking and writing up their approaching revival. Unfortunately the lambent flame of this ardently wished-for millennium has only scant warming power to it. At all events it has not yet warmed up many outsiders to enthusiastic co-operation in the efforts to revivify St. Raphaël out of its state of suspended animation. Even the electric light does not do away with the sombre feeling of depression that perforce comes over you, as you see everywhere the signs of an ineffectual fight for public favor.

The drainage system of the place is thoroughly French, and equally primitive. Everything is allowed to run into the bay, laving the fashionable promenade.

The house-drains are generally poor. No proper safeguards against the entrance of foul gases into hotels and lodging houses exist. There are a few exceptions to this general statement, but not enough to make it appear in any way exaggerated. It is not an ill smelling village, however, on account of the winds that purify the atmosphere.

Of course, the mayor knows that the drainage needs attention. A new sanitary system is promised. But with increasing experience on the littoral, the conviction grows that some of these local mayors are forever making promises that are forever being not fulfilled. They need a good shaking up to make them realize that foreign visitors want immediate action rather than prolific promises. Otherwise the non-progressive towns will be deserted in favor of such places as manage to keep abreast of the times.

It is claimed that the drinking-water of St. Raphaël is pure. But as it is drawn from a well, and in the absence of reliable analytical and bacteriological proofs, it would be but prudent to have it thoroughly boiled before use. Here again we are promised a new supply, the source being a mountain current in the Esterels. The works are to be completed this year.

An institution for the treatment of anæmia, scrofula, neurasthenia, and other conditions of a "run down" character, has just been opened here. The physician in charge, Dr. Lagrange, is a combination specialist of the ozone and hydrotherapy variety. Anybody who has enough constitution left to survive scientific cold water treatment, with superadded ozonic inflictions, ought to live long and die happy. If he don't, it is a private affair and need not be given to the public.

Fréjus.—This old town, only two miles and a half from St. Raphaël, is a highly interesting place to visit, on account of the Roman ruins found there. Agricola, the father-in law of Tacitus, was born there, and more recently (four weeks ago) Gladstone spent a few days at Valescure, a short distance from St. Raphaël. That is quite enough distinction for this immediate neighborhood, and we will now proceed to Grasse.

Grasse.—The circumstance that Queen Victoria had her spring residence at Grasse last year, has suddenly lifted into prominence this quaint, sleepy, old-fashioned little place. Grasse is picturesquely perched on the southern slope of Mount Rocavignon, which rises some seven hundred feet above it. It is about twelve miles by rail in a northerly direction from Cannes. The inhabitants, to the number of some fourteen thousand five hundred, are chiefly given over to the incessant production of perfumery. Rose, cassia, heliotrope, violets, jasmine, verbena, jonquil, tuberose, orange, mignonette, and other blossoms are squeezed in myriad numbers, till dying, they render the rich perfume of their souls to avaricious man.

In this respect the Grassois differ materially from other Riviera natives, who restrict the squeezing industry to the guileless foreigner. Numerous Rivierese manage in that way to extract some flavor out of life, without any damaging amount of exertion on their part.

Grasse gets plenty of sunshine, but being inland and some one thousand feet above the level of the sea, its climate is tonic, bracing, and soothing, rather than stimulating and exciting. It is a little colder than the coast places, but the rise and fall of the thermometer is less abrupt. Hence it enjoys a more equable temperature than do some of the better known and more fashionable resorts. Grasse faces the sea, and enjoys a charming view over the lowlands running down to Cannes.

Spurs of the Esterel Mountains extend to the northwest, and in a northeasterly direction there rise the peaks of the Alps. The dust and mistral are therefore less trying at Grasse than at neighboring stations, though the mountains back of the village fail to give it that complete protection which has been claimed for it. It will nevertheless be seen that Grasse possesses certain advantages that entitle it to be more patronized than it has been, at least by real invalids.

Not much has been done in the way of recent sanitary improvements. But the cesspool system is always less objectionable in small villages than in large settlements, where human beings are herded together in close quarters.

The Grasse drinking-water, while not absolutely irreproachable, comes from two good sources. It is conducted in canals, one of which is covered. It is safer to boil it before drinking, but it is less calcareous than much of the Riviera water. The two sources are known as *La Foux* and *Le Foulon*, and the supply is more than abundant. From the excellent little guide to Grasse just published by "An English Resident," the following table is taken:

ANALYSIS OF GRASSE DRINKING-WATER.

One litre of water taken at the sources contains:

	Foux.	Foulon.
Degree hydrometric	18.2	18 c.
Organic matters calculated as oxygen from permanganate of potash	7 mg. 2	0 mil. 48
Chlorides	traces	traces
Nitrites and nitrates	nil	very slight traces
Combined ammonia and albuminoids	0 m. 2	003 mil.
Oxygenation	8 cc. 5	8 cc. 2

A more accurate and satisfactory analysis than this one, I was unable to obtain.

The Grand Hôtel was put in good sanitary condition by Mr. Best, of London, prior to the Queen's occupancy. Board and lodging are cheaper in Grasse than at the more favored resorts. Many interesting walks and excursions offer themselves to the tourist. But apart from that there is very little "going on." It is for this reason, perhaps, that Americans are as hard to find there as the proverbial needle in the haystack.

Invalids who do not prosper at the sea-side will do well to try the inland air of Grasse; and for some cases of nervous break-down the very dulness of the place should be a strong recommendation. At Nice and other cities the sick are constantly tempted to indulge in unhealthful occupations and amusements.

Juan-les-Pins.—Travelling eastward from Cannes, this is the next station after Golfe-Jouan (Vallauris) has been passed, and before Antibes is reached. While it is very little known at present, the Juan-les-Pinets are hard at work to transform their sandy little desert into a real Riviera winter station. The place reminds the American visitor of a Western boom town, all staked out into lots, with grand sites for buildings that do not yet exist, and

plenty of room for every conceivable convenience that has not yet had the good luck to materialize. But it is quite true that one does find beautiful specimens of umbrella pines there. And then, again, people who take an absorbing interest in burying beetles, trap-door spiders, and other entertaining insects, will find plenty of opportunity to gratify their taste in that creepy direction.

Possibly the pine woods, together with the really fine sandy beach, will eventually commend Juan-les-Pins to some of the semi invalids that inundate the whole Riviera region. But the place is evidently too much exposed to winds for the enjoyment of a permanent popularity. The boom which is being carefully nursed there will probably be but a short-lived one. There are too many more favored spots in the immediate neighborhood.

Sanitation and Water-supply.—From a sanitary point of view it must be admitted that the new work is being well done, both as regards house draining and general sewerage. The water-supply is abundant, but of the quality of the water nothing definite has been learned. The water looks clear and limpid, and is devoid of odor. It is pleasant to taste.

Cap d'Antibes.—This new place is seven miles east of Cannes. Of Antibes itself it is unnecessary to speak, as it can hardly as yet be classed among the health resorts of the Riviera. Antibes is a very old fortified place, but, like Juan-les-Pins, it suffers too severely from winds to have much of a future as a health resort. People of slender means will find it a cheap enough place to live in, however.

Mr. Grant Allen has been very favorably impressed with another new spot some three miles distant from Antibes, and called the Cap d'Antibes. He says, evidently with some show of infatuation, that in addition to commanding the most beautiful views on the Rivieran coast, embracing at one glance the snowy Alps, the Esterel, the Bay of Nice, and the Golfe-Jouan, it is particularly adapted as a family health resort for autumn and winter. November there is charming. The Cape juts out into the pure sea some three miles or more from the town of Antibes; there is no dirty village close by, no doubtful drains, no regions of evil odors to be crossed before beginning one's stroll in the scented pine woods. Children have only to step outside the door to find themselves at once on the rocks of the sea-shore, or among unpolluted stretches of myrtle and lentisk scrub. In one word, they are here by the seaside and in the midst of the country; they can paddle and play with as great impunity in November and February as they could enjoy in England in fine August weather. He admits, however, that he does not consider the situation suitable for serious invalids, especially in advanced stages of phthisis. The Cape is breezy and airy, an admirable home for children or for adults who need sunshine and country walks and a warm southern climate. But very feeble people might find it too windy. At the same time, its intensely marine position, surrounded on three sides by the Mediterranean, makes a residence there much like passing a winter on a ship in genial sub-tropical seas; and the moisture in the atmosphere insures comparative freedom from the brusque changes of temperature experienced at sunset at Nice and Cannes. The spot, in short, has the usual equability of all peninsular climates. But it is a place, not for gayety, but for rest and quiet.

Mr. Allen mentions *en passant*, that he has no land for sale at Cap d'Antibes, and merely writes from the no doubt Quixotic desire to benefit his fellow-creatures. I have no information touching the purity of drinking-water there.

Beaulieu.—"Pretty spot," does not belie its name. It is also a relatively new place, at least so far as its pretensions to be considered a winter health resort are concerned. It is situated just east of the long, narrow peninsula of St. Jean. It is an admirably sheltered nook, famous for the size of its stately olive trees. Some (though by no means enough) good sanitary work has been recently accomplished there. Quite apart from this, however, the place is evidently growing in public favor.

Some Well-known Residents.—The Marquis of Salisbury has erected a fine villa there, situated on an eminence above the village proper. Sir Frederic Johnson, of sporting fame, and an "intimate" of the Prince of Wales, has spent many winters there. Mr. W. K. Vanderbilt and family also occupy the Villa Vial there this winter. A certain class of Americans always take an absorbing amount of interest in such personalities; and I expect their physicians to thank me for posting them. Only they need not all write at one time, and besides I am moving about a good deal this winter, trying to keep up my circulation and increase that of the MEDICAL RECORD.

Beaulieu is only three and one-half miles by rail from Nice, and seven miles from Monte Carlo.

The so-called potable water of Beaulieu is carried in a branch of the open canal de la Vésubie. As this water is not considered fit for drinking purposes at Nice, except after thorough boiling and filtration, these precautions should surely not be neglected by intending residents and visitors at Beaulieu.

The cesspool system here is not yet very objectionable, because the dwellings are far enough apart. In some of the houses a perfectly sanitary drainage system exists, but most of them require radical alterations to make them safely habitable. The few hotels are only in fairly good condition, and would be much improved by a thorough overhauling.

The situation of Beaulieu is such as to make it a more sheltered resort than Nice or Cannes. Accordingly it is rather warmer than those places, and its vegetation approaches more nearly the tropical character. For this reason it is often spoken of in these regions as "la Petite Afrique."

The Mediterranean forms a pretty bay at Beaulieu—in fact the original site of the place is a little promontory jutting out between two rounded bays. Black gives the following good description of the appearance of Beaulieu: "It is protected on the north by a range of gigantic cliffs (with patches of strata of reddish sandstone), the edges of which are fringed with trees; while below, groves of stately olive-trees cover the base and struggle as far up as they can by the fissures in the rocks. On the plain are orchards of orange and lemon trees and nursery gardens. Trees and tall shrubs hang over the edges of the abrupt banks, which enclose the tiny creeks and bays bordered with diminutive sandy beaches, or with long ledges of marble rocks dipping gradually down into the deep blue water, carpeted in some places with the thin flat siliceous leaves of the Posidonia Caulini, a Naiad not an alga, which covers the shore of the Mediterranean, and of which great accumulations are seen thrown up at various parts. It makes a poor manure, but prevents in some degree evaporation.

Disinfecting Food.—The Governor-General of Kiév appointed committees last fall to gather the morsels that are left on the table after meals in the large cities, and to send them to the famishing peasants. A large portion of this food comes from communal institutions, such as casernes, hospitals, and from social repasts. The question arose whether it would be possible to disinfect these fragments so that the contagious diseases of the eaters who left them on the table might not be conveyed to the beneficiaries without at the same time destroying the food. The question was referred to the Bacteriological Institute of Odessa, and the following instructions were received in reply: "Morsels of bread left over by persons infected with diphtheria, typhoid, or other contagious diseases, become perfectly disinfected if dried at a temperature of 250° F. But if such a degree of heat cannot be obtained in the drying process, the morsels, before drying, must be submitted to a current of steam of that degree for at least one hour."

THE ANCIENT HISTORY OF A NEW NEEDLE.

To the Editor of the Medical Record.

Sir: Probably "there is nothing new under the sun" in surgical needles, if we should look the subject up in Chesel den's "Armamentarium," or in ancient collections, and it is largely the fault of instrument-makers that old instruments are so often re-invented.

Grooved needles were devised by English and French surgeons before Professor Peaslee's time, but I think the first cannulated needles, made by boring a solid needle, straight or curved (Cleborne's tenacular needle), were made by G. Tiemann & Co., of New York, about twenty years ago, and still appear in the catalogue of that firm.

J. L. Mann, M.D.

Chelsea, Mass., May 13, 1892.

To the Editor of the Medical Record.

Sir: In your issue of May 14th I read the comments of Dr. Hahn and "Velus" on my hollow needle. Both mention needles of similar construction having been in use for years. I had never seen or heard of such an instrument when I devised this needle. It is singular that it never came into general use, since it is simple in construction, and I never had an instrument that gave better satisfaction for the purpose designed. Surely the clumsy knot in the silk forcibly dragging a loop of the wire through the tissue seems to me unsurgical, to say the least. Among all of the medical men to whom I showed this needle not one mentioned having seen one like it. While to me the idea was original, if to anyone else is due the credit of the device, by all means let him have it.

George Place Clements, M.D.

THE VIRGINIA MEDICAL LAW.

To the Editor of the Medical Record.

Sir: In your issue of May 7, 1892, you quote from the Boston *Medical and Surgical Journal* an erroneous statement to the effect that the Virginia law "regulating the practice of medicine and surgery," has been pronounced unconstitutional by the Supreme Court of Virginia in a case in which the Medical Examining Board recently prosecuted a Boston quack. The facts are as follows: This quack was prosecuted in the Hastings Court of Richmond City, and not the Supreme Court, and the case was decided against the Board upon the ground that the law was defective in that it failed to make specific provision for the registration of certificates of non-residents. The Court distinctly affirmed the constitutionality of the law in a letter to the President of the Board, setting forth the basis and scope of the decision. I quote the letter (Judge S. B. Witts) above alluded to, bearing date of April 14, 1892:

"1. I decided that the Legislature of the State has a right to pass laws regulating the practice of medicine in this State. Such a law comes clearly within the police power of the States.

"2. That the Legislature has a right to require non-residents to comply with the terms upon which it allows citizens of our own State to practise (129 United States, Dent *v.* West Virginia).

"3. That the Legislature not having provided a place where the non-resident physician may record the certificate required by law as a prerequisite to obtaining a license for practising medicine, etc., has imposed upon him a condition which it is impossible for him to perform, and therefore discriminates against him, such a condition amounting, in fact, to prohibition."

Such is the basis of this decision, and it cannot possibly apply in any other jurisdiction than that of the city of Richmond.

Some of the ablest lawyers of Virginia state that they believe the decision would be reversed by the higher courts.

This decision only applies to transients, and the law remains in full force with that single exception.

Jacob Michaux, M.D.,

Secretary Board of Medical Examiners of Virginia.

Richmond, Va.

New Instruments.

SOME NEW ADDITIONS TO THE ARMAMENTARIUM OF THE ELECTRO-THERAPEUTIST.

By A. Wilbur Jackson, M.D., F.S.Sc. Lond.,

Member of the Electro-Therapeutical Society, Paris, France.

Those practitioners who are accustomed to using electricity know how very large a field for improvement exists, both in the matter of instruments for administering the current, and in the means at our disposal for generating the same. In this short article I mean to put before the readers of this journal, in as brief a manner as possible, a description of some electrodes which I have had made for my own use, and which I believe will be appreciated by those members of the profession who may require such instruments.

Fig. 1 represents a combination hypodermic and aspirating syringe, with modifications. The cannula and needle, though represented in the figure, are not used by me. First, then, A is a binding-post for the positive reophore, leading to the battery; B is an extra long hypodermic needle, insulated to within a short distance of the point; D is a rubber sleeve, to be grasped by the fingers, insulating them; and E is a rubber button by which the piston is operated, thus insulating such parts of the operator's hand as would otherwise be exposed to the current. This instrument I have used in sciatica chiefly, putting the needle down upon the nerve, injecting slowly a preparation modified according to circumstances, and then turning on my current. Any further explanation would be superfluous, as such of the readers of the Medical Record as would care to use this instrument will at once appreciate its value. The negative electrode is placed under the corresponding foot and the cataphoric process is at once set up as soon as the current is turned on.

Fig. 1.—Jackson's Galvano-Hypodermic Syringe.

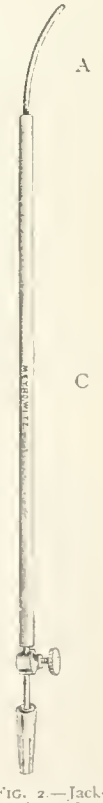

Fig. 2.—Jackson's Intra-Uterine Electrode for Plaster Tip.

Fig. 2 represents an intra-uterine electrode for positive cauterization or any other purpose for which the gold or platinum intra-uterine electrode has been used. A is a rod of No. 16 flexible wire, running snugly through the rubber sleeve, C. On one end of this wire is the socket for the rheophore tip, and above the tip is a sliding stop with binding screw, thus enabling one to adjust the wire tip to any length desired. The free end of the wire can be bent to any curve or shape desired. When adjusted, the operator has at hand a small saucer or cup, containing plaster-of-Paris mixed to a proper consistency with

water, and into this the tip of the electrode is dipped until enough adheres to it to be moulded by the fingers into proper shape for the purpose required. After this is done, the instrument should be laid aside until the plaster has attained the requisite hardness, when it is smoothed off with a little emery paper and is ready for use. If any medicament be required, such as ergotole, or any other fluid, the plaster may be charged with a given quantity, which it will readily absorb, and by cataphoric action "drive into" the tissue, as the snowy whiteness of the plaster when withdrawn will readily prove. If no medicament be used, the plaster, if very hard and dry, should be moistened with a little water. When the treatment is finished, the plaster is stripped off, the wire made aseptic with a bichloride solution, and it is ready for use once again. Thus each treatment is given with a perfectly new and clean electrode, and the diameter of the active portion of said instrument, as well as the depth of its insertion, etc., can be made just as the operator desires. To say nothing of the cost of the gold and platinum electrodes, this device will make intra-uterine work much safer and more efficacious.

Fig. 3 represents a common zinc electrode-disk, such as are used for sponges or absorbent cotton. With

Fig. 3.—Electrode for Cataphoresis, Plaster Covered.

such a disk, covered with plaster to a desired depth, and of a proper consistency, the writer makes his electrodes for cataphoresis. As directed in forming the intra uterine plaster electrode, the plaster should be moulded about the disk to the thickness of about one-eighth of an inch. When nearly hardened, the medicament is dropped upon it as upon the sponge or paper disks, and the instrument is ready for use. When the treatment is finished, the plaster is broken away and a new one made for the next time.

These devices have been in use by the writer for some time and answer their purposes fully, though I have no doubt but some reader of the MEDICAL RECORD will improve greatly upon each one of them.

The Messrs. Vetter & Co. made the second instrument for me, and the Messrs. Meyrowitz made the first one.

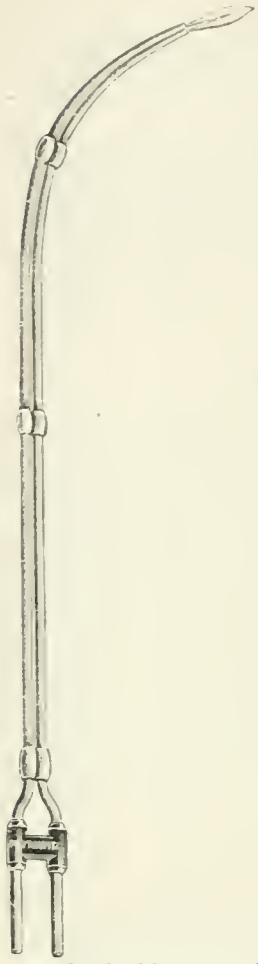
Anything regarding either of these electrodes that may require further elucidation will be explained with willingness if the inquirer will address his queries through the columns of this journal to the writer.

Hot Springs, the Doctors, and the Touters.—The following circular was adopted by the Hot Springs City Council, March 1, 1892: "Don't listen to any one who volunteers advice about doctors. No regular physician will require more than $5 in advance. If you have letters to a physician, deliver them in person. If drummers find you have such letters, they will tell you the doctor is out of the city, dead, quit practising, drunk, or something of the kind. Drummers on the trains, on the streets, or at the hotels or boarding-houses will pretend that they are visitors."—*Weekly Medical Review.*

Vaccination in Italy.—The *Sanitary Inspector* states that a new vaccination law went into effect in Italy with the beginning of this year, which requires that every child shall be vaccinated before it is six months old, and again at eight, or at any time whenever the sanitary authority deems it necessary to promote individual or public safety. Those who are not vaccinated and revaccinated according to the requirements of the law, are excluded from schools, factories, workshops, benevolent institutions, etc. Provision is also made for the cultivation and supply of both animal and human lymph. This has a direct interest for people in this country in view of the large and constantly increasing Italian immigration.

A NEW NASAL ELECTRODE.

By LEONARD A. DESSAR, M.D.,
NEW YORK.



THE risk of infection from the use of the ordinary cautery electrodes led me to the idea of devising an instrument by which this danger might be obviated.

Mucus and pus are apt to collect on and about the binding cords of the ordinary electrode and so become a source of infection, as it is almost impossible to cleanse these instruments thoroughly.

At my suggestion the Messrs. Meyrowitz have constructed a set of electrodes made of metal which, when not in use, may be immersed in a solution of carbolic acid or other disinfectants and thus rendered perfectly aseptic.

Another advantage of these electrodes is the fact that they can be heated to the proper degree with a weaker electrical current than those in ordinary use. The instruments are made of copper, nickel-plated, and the shafts are united by two metal bands, the insulating material used being ether fibre, asbestos, or ivory.

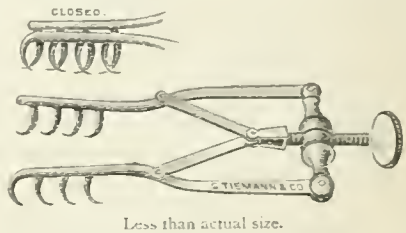
The idea first presented itself to me in Vienna last summer, and I am indebted to the instrument maker, Marconi, of that city, for a number of valuable suggestions regarding the manner of its construction.

SOME NEW EAR INSTRUMENTS, WITH REMARKS ON THE TREATMENT OF CHRONIC PURULENT INFLAMMATION OF THE MIDDLE EAR.

By FRANK ALLPORT, M.D.,
PROFESSOR OF CLINICAL OPHTHALMOLOGY AND OTOLOGY IN THE UNIVERSITY OF MINNESOTA, MINNEAPOLIS, MINN.

I DESIRE to call the attention of the profession to a modification of a recent instrument, and to two new ones.

Some time ago I published a short sketch of what I termed a "Mastoid Retracting Speculum." Since then this instrument has been frequently used by myself and others, and proved to be invaluable in mastoid operations. Having altered the handle, or screw-head, I take the liberty of again bringing it to public notice.



Less than actual size.

As originally made, the handle or screw-head was round. It was found that when the arms of the instrument were engaged in the wound, the round screw-head did not permit of its utmost expansion. This was undesirable, as the wider the arms were opened the larger became the field of operation, and the more thoroughly the hemorrhage was stopped; consequently I have caused the screw-head or handle to be made flat. It will be seen at a glance that this gives much more power to the instrument, and materially increases its usefulness.

Allow me to call attention again to the method of using this instrument, and to some of its advantages. In making a mastoid operation it is desirable that the two flaps made by the incision be forced widely open, in order that the work upon the bone may be kept well under observation. The arms of the speculum can be closed or opened by the screw-button at the base of the instrument. The hooks are made to interlock nicely, so that they can be introduced into quite a small aperture. The hooks have sharp, but not cutting, points, and the whole instrument is made strong and short, in order that considerable force may be used in opening the blades, which may become necessary in case of great thickening or swelling of the tissues over the mastoid process. The instrument may be introduced into the incision with its base either up or down. When thus introduced and widely expanded, and the parts wiped as dry as possible, a fine view of the underlying bone may be obtained, and the ease of the operation much facilitated. The wide expansion of the blades renders the operation practically bloodless. I am quite positive that anyone who has used this instrument once for a mastoid operation will never operate without one. It is so easily handled, so simple, so practical and useful, that it is really indispensable. With a modified handle I regard it as a perfect instrument. I will remark in passing, that this instrument would be exceedingly useful in any operation in any part of the body where we wish to hold open a wound. A large instrument made upon this model would be valuable for holding open the incision in a laparotomy. It can be modified to be used anywhere, for holding open incisions, and I am confident might be invaluable.

The speculum, as well as the other instruments spoken of in this article, are made for me by Tiemann & Co., of New York.

The second instrument to which I desire to call attention, I have called a "Round-pointed Ear Hook." It is exceedingly useful for a great variety of purposes, but was originally designed by me to facilitate the removal of carious ossicles. It seems difficult to understand why chronic suppurative inflammation of the middle ear should not be treated on much the same general plan that controls the treatment of other suppurating cavities or surfaces. The cardinal points in such treatment are the removal of all unhealthy products and the keeping of the parts in as nearly an aseptic condition as possible. These aseptic principles, it is to be regretted, are often neglected in the treatment of chronic purulent inflammation of the middle ear. The aurist is too often satisfied with following a stereotyped plan of procedure. This consists in cleansing the ear with a syringe and some antiseptic fluid, and then drying the parts. This is followed by the insufflation of some antiseptic powder, such as boracic acid or iodoform. Any polypi that may show themselves will be very properly removed and their bases cauterized. Any necrosed bone that may be especially prominent will be removed or touched with some bone-destroying remedy, such as aromatic sulphuric acid. This, in brief, is the usual plan adopted in the treatment of such diseases, and in a proportion of cases it may be quite sufficient to produce a slow but satisfactory termination of the case. But in a large percentage of such cases the result is unsatisfactory to both patient and physician. An apparent cure may be effected and the patient dismissed, only, however, to return after a while with a full recurrence of his trouble. Or a patient may be treated month after month with ordinary methods, without effecting a cure, or even an apparent cure. The trouble with these cases will usually be found to be hidden necrosed bone. Its removal will generally effect a speedy and permanent cure.

At the commencement of treatment of chronic suppurative inflammation of the middle ear, a thorough and painstaking examination should be made. It would hardly seem necessary to urge this principle, and yet the careless and routine method of examining such cases, employed by many physicians, seems to render it important to advocate an accurate diagnosis before further steps are taken. The examination should include not only what can be seen by the eye, but should extend into the middle-ear space, with special reference to that portion of the middle ear known as the attic. It is here that serious trouble will be found in a great many cases. The malleus, incus, and stapes may be found necrosed, and treatment may continue interminably until this element of disease is eliminated. The malleus is most frequently necrosed. These diseased points must be searched for diligently, and for this purpose straight and bent probes must be employed. The latter will be found especially useful in searching for necrosis in the attic of the middle ear. The little probe that comes on the other end of an ear-spoon answers a very good purpose in these cases, and when used carefully and turned in every direction, will usually find the diseased bone if any exists. It is, of course, in hidden parts of the middle ear that necrosed bone does the most injury, because, owing to its obscure position it is usually overlooked. The necrosis that presents itself in easy view does but little harm, as it has already nearly loosened itself from the deeper parts, and will either come away by itself, or be easily picked away with the forceps.

In old cases of chronic purulent inflammation of the middle ear, the little bones are exceedingly prone to necrosis, and they have a tendency to pull themselves together. As this contraction progresses, they sink toward the inner wall of the middle ear, and are often deposited in the extreme upper and inner part of the attic, where they may be felt as an irregular, necrosed mass. Sometimes this huddling together of the little bones occurs even though there be no necrosis present. In this event, they are still a source of irritation, may be quite easily felt with the bent probe, and should be removed. In this position necrosed bone does great damage, and must inevitably produce and retain a foul and unhealthy purulent discharge. It certainly appeals to good judgment to advocate the removal of this mass before the cure can be expected. Surely no surgeon would expect to cure a diseased joint until the necrosed bone present was destroyed, and yet physicians are daily endeavoring to cure suppurating ears, without first making an accurate diagnosis, and afterward removing any necrosed bone present.

The researches of Sexton and others are exceedingly valuable, in that they have called attention to this more scientific method of treatment, but the methods employed by them are so painstaking and elaborate as to dissuade surgeons from operating. I have operated upon many such cases and have obtained good results, and yet the method pursued by me is so simple as to discourage no one. I operate on such cases without any elaborate preparation, without general anæsthesia, without a large assortment of instruments, and with but very little pain and discomfort to the patient. Such cases are operated upon by me in an upright position with cocaine anæsthesia, and, so far as I can see, my results are equal to the published records of Sexton and others. To facilitate this operation I have devised the "Round pointed Ear Hook," already mentioned, a cut of which is here shown.

The handle is represented as broken. Otherwise it is of actual size.

The malleus is removed with comparative ease, and as it is the bone most frequently necrosed, the facility of its removal is quite fortunate. Oftentimes this is the only bone diseased, and its loss will then be followed by a cure.

All that is usually needed for its removal is a narrow knife with which to circuitously incise the drumhead, in order that the bone may be loosened in its attachments. The ear hook is then introduced behind the drumhead and

malleus, and its point forced as high up in the attic of the middle ear as possible; the hook is then firmly and steadily withdrawn, keeping the point up as high as possible. The malleus, and occasionally the incus, will be found to come with it. The bone, or bones, may then be withdrawn by means of Sexton's admirable ear-forceps, or my "Smooth Ear Curette," referred to later in this article. The incus is more difficult to remove than the malleus, and its extraction is frequently unnecessary; but, if its removal is deemed advisable, it will usually be found lodged high up in the attic of the middle ear. The extraction of the malleus will, however, somewhat loosen its attachments, and by means of the ear hook it can be coaxed down into sight, and then withdrawn by means of the forceps or curette. The stapes is much more difficult to extract than either of the other bones, and it is usually advisable to leave it alone. It is very small, and if carious, will usually either be absorbed, or else some day, during the course of treatment, will drop down into view of itself, and can be easily extracted. This operation should be followed by daily treatment, consisting largely in syringing and antiseptic powders, and will usually result in a speedy cure.

Less than actual size.

It will be noticed that the ear hook is round-pointed, in order to avoid scratching or tearing the parts. Its point is bent backward, so as to facilitate the removal of bone, foreign bodies, etc., and is rather long, so as to enable it to be placed high up in the attic, or other obscure places.

The ear hook may be used as a sort of general utility instrument in the ear, for the purpose of picking away various products, such as inspissated cerumen, desquamated skin, etc., but is especially useful where such products are retained in spaces above or below the direct line of the meatus. In such cases the point of the hook may be thrust to the bottom of the hidden place, and the wall gently scraped with the round point in such a manner as to afford a thorough cleansing of the parts.

Another instrument that I have devised, and found useful for the extraction of various foreign bodies from the meatus and middle ear, is what I have termed a "Smooth Ear Curette." It is simply a smooth wire loop, placed upon the end of a delicate handle, as seen in the engraving. Cases are often observed where the meatus needs to be cleansed of various foreign substances, where the use of an instrument with a sharp or cutting edge would be undesirable; in such cases this little instrument will be found of practical utility.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending May 21, 1892.

	Cases.	Deaths.
Typhus fever	2	0
Typhoid fever	13	5
Scarlet fever	233	27
Cerebro-spinal meningitis	8	8
Measles	807	38
Diphtheria	131	35
Small-pox	9	1
Varicella	0	0
Pertussis	0	0
Erysipelas	0	0
Leprosy	0	0
Mumps	0	0

The Itching of Eczema is relieved, according to Shoemaker, by the frequent application of equal parts of lime-water and glycerine.

Fowl Language.—The *Boston Medical and Surgical Journal* says that M. du Haudray, following the method of Professor Garnier's studies of the Simian language, has carried his phonograph into the hen-coop. He places it in one hen-house where the "family" are at home, and when the receiver has been cackled into for half an hour it is taken away, and made to repeat all the gossip in a neighboring hen-coop. The results of the experiments are said to be marvellous, and the Académie des Sciences is awaiting a lecture on the subject with the greatest interest.

The Foot-ball Casualties in England during the season of 1891–92 amounted to eleven deaths and seventy injuries. This is worse than the prize-ring.

A Folk-Lore Remedy for Enurosis.—A surgeon in Hampshire writes to the *British Medical Journal* that he was consulted by a mother concerning her little boy who suffered from nocturnal incontinence of urine. She said that before consulting the writer she had, on the advice of an old nurse, caught a mouse, killed it, roasted it, and given it to the child to eat, and that the nurse informed her the remedy was an infallible one, a dictum which the events of the next night disproved. She did not tell the child the nature of his meal, which he ate and enjoyed very much. The mother in question did not belong to the uneducated classes.

The Use of Vaseline.—Dr. Novotny warns against the use of vaseline as a lubricator for sounds and other instruments introduced into the bladder, as he has twice found this insoluble vaseline serving as a nidus about which a mass of detritus had collected, and giving opportunity for the deposit of urinary sediment. In one case the quantity of detritus thus massed together upon a quantity of vaseline weighed ten grammes.—*Memorabilien.*

INFLUENZA AND THE LATEST BACTERIOLOGICAL RESEARCHES.[1]

BY F. J. THORNBURY, M.D.,

EX-SENIOR RESIDENT PHYSICIAN, CINCINNATI HOSPITAL.

AN attempt at tracing influenza to its origin embraces a review of the history of medicine and an encounter with its various decades in pathology and therapy. The disease has prevailed through many centuries, and is said even to have been known to Hippocrates. Others again claim that not until the time of Sydenham have we fully authenticated accounts of its existence. The occurrence of an epidemic, however, about the middle of the eleventh century, can be fairly well substantiated, and recorded in medical history are accounts of subsequent epidemics, recurring at intervals varying from two to seventy five years up to the present decade.

It is stated in many instances that the disease came from Asia, usually Siberia, crossed over to Russia, and from there disseminated itself over the whole of continental Europe and the British Isles, after which it reached America, Australia, the East Indies, and, finally, all parts of the globe.

Usually with great rapidity have the individual epidemics progressed. Climatology, meteorology, and barometrical influences, coming after a long list of absurd hypotheses, were invoked by the ancient contemporaries to explain the occurrence and rapid spread of this mighty malady. Striking accounts as to extent and mortality are given in the annals. During the epidemic of 1580, which occurred in both of the world's hemispheres, hundreds of thousands were prostrated. In Rome two thousand people are said to have died on the first day of the invasion.

In 1675 Sydenham wrote of influenza: "It spread from east to west over the whole earth, and coughs prevailed to an extent never before seen in my existence—no one escaped, whatever might be his age or temperament, and it ran through whole families at once."

In the epidemic of 1729 and 1730 Vienna had 60,000 cases, Rome, 40,000. In London 908 deaths occurred in one week.

The influenza which announced itself with the beginning of the eighteenth century prostrated five-sixths of the inhabitants of Poland and other countries of Central Europe. One hundred and twenty-three cities of Great Britain were visited, and the disease made great havoc among the aged and infirm. There are nervous, catarrhal, and gastric forms described, many relapses occurred, and often serious complications ensued.

I find accounts of forty-two different influenza epidemics in all, extending over a period of about five hundred years. One epidemic of the seventeenth century was described by seventy eight different writers. Fothergill was the American exponent.

With this brief synopsis of the history we come now to the recent epidemic of 1889, 1890, and 1891. In the summer of 1889 influenza began in Siberia and reached St. Petersburg in October. Here 150,000 of the inhabitants were attacked, the schools had to be closed, and business was suspended. Some cases assumed a typhoid, others a meningeal, character, and confusion occurred in diagnosis. In Berlin, January, 1890, of 170,318 school children, 11,532 had influenza. Measles, pertussis, scarlet fever, and diphtheria were conspicuously absent, and seemed to have been swept away by the influenza. In all the capitals of Europe the disease became prevalent—the approximate proportion of the population actually affected was finally placed at one-third to one-half per cent. In Vienna there were 450,000 cases. In Paris, of 1,200 cases reported to the Health Office in one day, 1,050 were influenza. In Madrid, Spain, there were 20 000 cases, and more deaths than during the cholera epidemic of 1885.

Isochronous the disease occurred in America; ships on the open sea were attacked. One vessel, five days from Yokohama, had an epidemic on board. Remote islands were visited.

A tendency toward pandemicy and quite close confinement to certain localities has often been manifested by influenza. At Chicago, during the winter of 1890 and 1891, the disease was most violent and disastrous, especially among the laboring classes. Sixty deaths are said to have occurred in one day. At Buffalo the disease also prevailed extensively, while intervening Cincinnati enjoyed a partial temporary immunity. Of over five thousand cases which I examined at the Cincinnati Hospital during the year, but eighty-seven were cases of influenza, and only forty of these sufficiently severe to require admission to the hospital.

With reference to the etiology of influenza, it occurs in all zones and all climates and at all seasons of the year, showing a predilection, however, for fall, winter, and spring, and the temperate zones. People of all ages and occupations are eligible to the disease, and it shows no particular preference for either sex, although males are probably more often attacked, as they are more exposed. As to the actual specific cause, we have it in the recently discovered bacillus. The latter is as firmly established as most of the facts which we have in medicine. The germ has been seen, isolated, cultivated, and inoculated by two of our most ingenious bacteriologists. Their observations have been corroborated by the Father of the Science.

In every case of a series examined by Richard Pfeiffer this bacillus was found present in the sputum and in the protoplasm of the cells of the bronchial exudate. The numbers of bacilli present are in direct proportion to the degree of pyrexia. As the symptoms of the disease subside, the bacilli also disappear, and are not to be found after there is fever. They penetrate into the peri-bronchial connective tissue, and may even aggregate in pure cultures on the inner surface of the pleura.

The influenza bacillus is of very diminutive size, being only one-half as long as the septicæmia bacillus, but having about the same thickness. With diluted Ziel's solution and heated Loffler methyl blue, it may be stained very readily, as will be seen in the specimens presently to be demonstrated. The germ grows best in sugar agar, one and one-half per cent., and may be cultivated to the fifteenth generation, as has been done by Kitasato. The colonies appear as minute watery drops along the streak of inoculation. In bouillon the bacillus grows scantily and gives evidence of its immotility by the fluid remaining clear. In gelatine it cannot be cultivated, owing to the higher temperature which it requires. (Gelatine melts at 28° C.)

Canon, at Moarbit Hospital, Berlin, has found this ba-

[1] Paper read before the Alumni Association Medical Department of Niagara University, Buffalo, N. Y., May 2, 1892.

cillus in the blood in twenty consecutive cases of influenza. A coloring solution of concentrated methyline blue and eosin in alcohol was employed. The blood-corpuscles are thus stained red, while the bacilli have a contrasting blue color. Usually they will be seen in clumps in the field—ten to fifty being aggregated in one spot. Occasionally, however, these clumps will appear as if spread apart and each individual bacillus will be distinctly seen separated from the others in the group. These clumps of bacilli floating in the blood are capable of producing embolism, by stopping up some peripheral capillary, and may thus explain some of the many complications characterized by the formation of abscess—suppuration being the natural consequence of septic embolism.

The presence of the influenza bacillus in the blood and sputum is of positive diagnostic value, and by microscopic examination we can state whether or not an individual case is one of influenza.

The final and convincing link of evidence in favor of this bacillus is the fact of our being able to communicate the disease to animals. Apes and rabbits present quite typical influenza after inoculation with the Pfeiffer-Kitasato bacillus. It seems reasonable to conclude, therefore, that this bacillus stands in direct causative relation to the disease. It is found in all cases of influenza; it is not found in other conditions; its inoculation communicates the disease to animals. Organisms have been seen by other investigators. Kleb's flagellaten is well known, but never was seen by anybody excepting himself. Weichselbaum found the pneumococcus so frequently in association with influenza and its various complications that he was inclined to attach a specific importance to its presence. All of the pus-formers have of course been seen. It seems rather unscientific, however, to search for the specific cause in abscess cavities.

The now authenticated bacillus doubtless has been seen by other investigators, but to isolate it, stain it, recognize its growth on agar, and decide that it was a bacillus and not a diplococcus, remained to reward the efforts of Pfeiffer, Kitasato, and Canon.

It was the heavy staining of the end pole and the overlooking of the clear, watery drops of diminutive size, representing the growth of the isolated colonies on agar, which misled the previous observers. During the past month there has been some interesting corroborative work done in Paris and Germany.

MM. Cornil et Chantemesse inoculated the Pfeiffer-Kitasato bacillus into the anterior chamber of the eye of rabbits. In a few days the rabbits showed evidence of a disease simulating influenza, and the bacilli were found in the blood.[1] Some of the latter fluid kept in sugar-bouillon for twenty-four hours was injected into the nostrils of a monkey. The next day the animal had coryza, high fever, diarrhœa, was prostrated and stupid for several days, but finally recovered. The bacilli are found in the nostrils, mouth, and bronchial secretion. Mice inoculated died in four days, and the lungs showed hyperæmia and ecchymosis; the kidneys were swollen and hyperæmic, and the bacilli were disseminated through the other visceral organs.

The medium employed by Professor Babes in the cultivation of these organisms is of the following composition: Agar agar, 1.5 per cent.; glycerine, two per cent.; peptone, two per cent.; chloride of sodium, five per cent., in neutralized bouillon.

Canon cultivates the bacillus from the blood by obtaining eight to twelve drops of this fluid in Petrie's glasses containing glycerine agar, and kept at 37° C. With the Pfeiffer bacillus, cultivated from the thick purulent secretion covering the mucous membrane of the respiratory tract in a case of influenza which terminated in a fatal bronchial pneumonia with meningitis, rabbits were inoculated and died in twenty-four hours; one succumbing to diffuse abscess formation. The presence of not only the streptococcus pyogenes, but also the short Pfeiffer bacillus, was established by microscopic examination and culture experiments.

[1] Bulletin de l'Académie de Médecine.

Erosions of the Schneiderian mucous membrane in cases of influenza showed compact thick layers of a very small bacillus embedded in a covering of tenacious mucus. These bacilli penetrated into, and completely filled, the epithelial cells, and leucocytes were found in aggregated clumps in the superficial lymphatic channels.

The epithelial structure itself, with the serous and cellular exudate, forms in a necrotic degree, and there is found small round-cell infiltration of the deeper layers of the membrane. The visceral organs are permeated by the bacilli. The lymph-vessels are swollen and contain yellowish thrombodic masses. Professor Babes claims to have seen other varieties of organisms present. He describes exquisitely fine-pointed diplo-bacteria occurring in chains, and small immotile rod-forms containing a contrasting granular nucleus, around which is a light colored zone; they color to varying degrees of intensity with the aniline dyes, and do not, with the exception of the chromatic nucleus, stain per Gram's method. The germs are pathogenic for rabbits and white mice. Inoculation on the unabraided nasal mucous membrane leads to a form of fatal septic pneumonia. Letzereich's reports are throughout substantiating, and he adds the additional evidence that the bacillus grows on potato at 30° to 37° C., luxuriantly for a short time, the colonies having the usual transparent or drop-like appearance, or may form in elevated streaks over the surface. But after about forty-eight hours the colonies become covered up by overgrowth of micrococci and streptococci present in the bronchial mucus which has been spread over the surface of potato; with methyline violet the bacilli colors red, the ends dark red, seemingly by reason of an aggregation of the protoplasm. The latter seems very suggestive of an endo-spore in this bacillus. A highly refractive granular nucleus had already been referred to in Babes's report, and such a compact, resisting, and refractive protoplasmic body in a bacillus, with sharply defined contour, formed by a coalescence of the minute granules, about corresponds with the definition of a spore; and I believe that further work in the longer staining of this bacillus will reveal this refractive nucleus to be a spore. Thus we see that the latest French and German investigations, and those of Professors Babes and Cornil, in particular, seem for the most part to corroborate the work so thoroughly done by Pfeiffer, Kitasato, and Canon. Certain differences, however, we must admit, as in the finding and cultivation of varied forms of these pathogenic organisms by Babes; but, notwithstanding, a valuable contribution has been made to science, and its perfection will place it among the great advances of the present eventful decade. Through five long centuries has the actual cause of influenza remained in obscurity, and now, for the first time in the history of medicine, are we able to classify this disease with tuberculosis, cholera, typhoid, diphtheria, anthrax, and certain other diseases as positively infectious, and whose etiological nature we understand, and can isolate and inoculate at our disposal.

The presence of influenza spores in the bacillus will explain much that we have till now been at a loss to account for in the occurrence and spread of influenza epidemics, and the occurrence of obscure isolated cases on ships at sea and in remote islands.

We all recognize the wonderful endurance of spores. They are the most resistant form of animal life known to us. Extremes of heat, cold, and chemical action have little influence upon them. The spores of anthrax will tolerate a temperature of over 140° Celsius, for three hours, before losing their virulent properties. They live indefinitely in the ground or elsewhere, and after years, when brought, accidentally perhaps, into circumstances favored by heat and temperature, they segmentate and produce disease. The anthrax spores on threads used by Koch in his investigations in 1882 are still preserved in

the Hygienic Institute at Berlin, and produce anthrax to day as typical and as fatal as they did ten years ago.

It would seem, then, that the influenza bacillus must have a correspondingly resistant spore, when we consider that at times for fifty years the disease has been, so to speak, dormant, and in no part of the world in pandemic existence.

By reason of their characteristic form, size, and color, the influenza bacilli may be easily differentiated from other micro-organisms—streptococci and micrococci, so common in the sputum. Pfeiffer's observation of the capability of these bacilli penetrating through the peribronchial connective tissue and congregating on the inner surface of the pleura, as was seen in two cases at autopsy, supports the evidence of the highly virulent and infectious nature of these germs, inasmuch as other pathogenic bacteria have also the power of aggregating and localizing themselves, and through their proliferation and production of poisonous ptomaïnes can produce local ulceration, suppuration, and constitutional infection.

We have, in the past two weeks, accounts of 50 cases of control experiments by Letzereich, of Wiesbaden, in which examinations in other infectious diseases, viz., measles, scarlet fever, diphtheria, pneumonia, and in catarrhal affections of the respiratory passages, showed that in no instance, either in the blood or in the sputum, is this bacillus to be found. It is present only in the blood and bronchial secretions of influenza patients. Is not such evidence convincing? As previously intimated, this new bacillus does not imbibe particularly well the applied coloring matters. Only with difficulty and under particular circumstances do they take the aniline colors. In a weak alkaline, aqueous solution of methyline blue they will not stain at all. On the other hand, if they are placed in methyl violet, heated for two or three minutes, a striking peculiarity is presented. They do not appear of the color they have taken up, but much redder—a bright rosy color. Only in these bacilli with the protoplasmic thickening at one or both ends is there a red-violet shading, and in the latter instance the dark interior nucleus is plainly visible by means of a one twelfth oil emersion Zeiss and the Abby condenser.

The ovoid form is especially easy of recognition in the bacilli with protoplasmic thickening and darker-stained ends.

From the beginning of the disease the bacilli are present in vast numbers in the blood, and during its further course they gradually diminish, and, finally, after a certain form of "protective" treatment instituted by Letzereich, the coloring matter is no longer taken up by the bacilli; they then have a pale, insipid, barely recognizable appearance in the blood and sputum. Finally they disappear entirely. The entire duration of their presence in uncomplicated cases varies from five, eight, and ten to fourteen days. Where there has been lung inflammation resulting, for three weeks many of the bacilli can be seen. These very minute protoplasmic germs find an easy dissemination through the atmosphere, especially in the dry air of the sick room and hospital wards.

The intimation of something like a protective treatment by Letzereich, of which he promises soon to give further account, may be awaited with much interest.

Why, then, shall we not concentrate our attention in bacteriological research, when it has done so much in the illumination of avenues in our science ever before obscure? This has been a decade characterized by the revelation of the cause of disease. The next ten years will be an immunity period, a period for the cure of those maladies whose cause we now understand and have under laboratory control. The first principle involved in all treatment is to know the cause. In absence of this understanding of cause, we are working in the dark and cannot scientifically influence effect. The underlying philosophical law, then, is perfecting itself. The natural consequences will be sure to follow. The good effect of the facts enunciated, and substantiated through bacteriological revelations, are becoming strikingly apparent in prophylaxis. How many thousands of lives have been saved in surgery and midwifery by the knowledge of the disastrous consequences of sepsis and the logical institution of asepsis. With this slight digression an attempt at concisely summarizing the clinical history of influenza will now be made. The latter subject, comprising the course, duration, and termination, is a rather extensive chapter.

After a period of incubation varying from twenty-four to seventy-two hours, the disease announces itself with the usual prodromes of general malaise, headache, languor, etc., and may run a short course and be attended with mild symptoms.

On the other hand, a most sudden and violent onset, with extreme prostration and alarming complications may be the character assumed. Symptoms referable to the nervous system, as a rule, are the more prominent. Influenza has been looked upon at times as a cerebro-spinal affection. It is the prostration which stands in the foreground. To extreme extent, and almost invariably, it is present. As early as the year 1800 Metzger directed attention to the weakness and prostration in influenza. Patients attempting to stand felt as though they had arisen from bed after a long protracted illness, were often attacked with vertigo, and fell into a syncope.

Gluge, the great influenza historian, dwelt especially upon the prostration. It was observed in the strong and robust, in youth and in the aged, affected not only the motor and sensory functions, but there was also depression of mind and of spirits. Pronounced melancholia, hypochondriasis, and hysterical manifestations, as will later be seen, are not uncommon. Loss of energy and will power, a cloudiness of the psycho-sensory sphere, stupor, sopor, and complete coma, are recorded by Bokel, and speak for a direct working of a chemical poison on the cortical brain-centres, probably the ptomaïne products of the bacillus which produces the disease.

Second in importance and frequency stands the influenza headache. It is characterized by its enormous intensity, being out of all proportion to the temperature range and other symptoms. Even in mild cases the headache is severe, and constitutes the chief symptom in the disease when catarrh and gastric disturbances are only moderate. This pain in the head is of a deep meningital character, and is often suggestive of this condition, especially as there is not infrequently an associated slowness of the pulse. Carmichael Smith, in 1782, made these classifications of cephalalgia in influenza. The first was an uneasy weight, soreness, and distention feeling as in common colds. Second, the violent sick-headache arising from affections of the stomach, and relieved by vomiting. Third, the sharp lancinating pain, as if the head were splitting. Fortunately, this more extreme suffering is of but short duration. Belonging to this same category migraine and hemicrania may be mentioned.

Also supra- and infra-orbital, trigeminal, sciatic, and intercostal neuralgia. Delirium is by no means rare, and was observed as long back as we can find accounts of the disease. It may be mild or transitory, or of a wild and recurrent character. Hyperæsthesia, anæsthesia, deafness, tinnitus aurium, photophobia, and diplopia may develop. In the circulatory system the pulse first attracts our attention. It is usually increased in frequency and may be quite rapid. Slowness of the pulse to 48 has been seen by Whitenmeyer. Very frequent and insidious is a cardiac weakness, which may become extreme and may lead to a sudden death. Indications of vaso motor paralysis is afforded by erythemas. One author speaks of an angio spastic condition with extreme pallor. Hyperhydrosis accompanies many attacks and may continue after the attack has subsided, the patient perspiring profusely upon only slight bodily exertion. Sweating and prostration seem to go hand in hand. The temperature in influenza may be anywhere from 98° to 105° F. In

Leyden's clinic, during the past few months, many cases showed an irregular temperature curve. The catarrhal symptoms will now engage our attention. As early as 1883 Faulkner spoke of a nasal catarrh, catarrh guttural, and catarrh bronchial. A combination of rhinitis, pharyngitis and laryngitis, rachitis and bronchitis, may comprise the clinic picture. Paroxysmal suffocative attacks, without much local disturbance, may be experienced, and are seemingly of central origin. The mere mention of influenza implies cough and expectoration—an acute catarrhal process; but the symptoms on part of the respiratory tract are not always predominant, as previously shown. Epistaxis and bloody expectorations, without phthisis or pneumonia present, are mentioned by Leichtenstein.

Letzereich, of Wiesbaden, in the last issue of the *Zeitschrift fur klinische Medicin*, states that at various intervals in influenza, trachitis, and bronchitis, there is an aqueo-sanguineous expectoration very similar to hypostatic sputum. This blood-tinged secretion contains myriads of the bacilli, especially during fever exacerbations. The germs, however, are never entirely absent at any time in the course of the disease. They are constant in every specimen of the blood examined, without exception. Symptoms on the part of the digestive apparatus are rather less prominent than those of the nervous and respiratory systems, although a cholera like enteritis and dysenteric dejections have many times been observed in past epidemics.

As a rule there is anorexia, and there may occur vomiting. A peculiar saccharine odor of the breath has been noted by English clinicians. Baumler says that in nearly all of his cases a slight icterus was present. Regarding enlargement of the spleen in cases which came to autopsy, there seems to be a difference of opinion. Ewald and Virchow have observed it. Biermer claimed for it a differential importance; others again have failed to find any spleen tumor.

The urine in influenza is naturally of febrile character, and is increased in quantity as a rule when no fever is present. Alison speaks of a great tendency toward formation of a sediment.

Weichselbaum has seen in the urine the diplococcus of pneumonia. Spectroscopic analysis reveals the presence of modified biliary coloring matters—chromogen and urobilin. The former was found regularly by Chapelle, with, also, hyper-acidity. Cambe held increase of phosphoric acid as an indication in therapy. Skatol and its combination with sulphuric acid has been recognized. Albuminuria is not infrequent. Aneuria occurs.

The liability to pneumonic complications in influenza we find substantiated as far back as it is possible to trace the history of epidemics. Before speaking of pneumonia, however, there are a number of other sequels to be noted, which belong to this category. A sub-chronic or chronic laryngitis is probably most common; angina follicularis is a frequent association. Circumscribed ulceration of the vocal cords has been described by three different writers. Œdema of the glottis, consecutive to a diffuse phlegmonous laryngitis, I have myself seen. A flaccid palate, from paralysis of the azygous muscle and paresis of the pharyngeal constrictors, while not so common as in diphtheria, does occur in influenza.

An influenza bronchitis, without any inflammation of the lungs proper, is not seldom the cause of death in the aged and debilitated. The liability to the development of pneumonia is very great, and it is this complication which is accountable for a large contingent of the mortality in influenza.

The German pathologists have classified it in a fibrinous lobular, fibrinous lobar, and a catarrhal form. The prognosis, especially in the aged, is very unfavorable. Of 174 cases of influenza reported by Mason, 77 had pneumonia; and the mortality with those in the fortieth to fiftieth year was forty-five per cent.

In children, on the other hand, pneumonia is rare as complicating influenza. It occurred but once in 218 cases, according to Comby, and he expressed the opinion that broncho-pneumonia after measles was favorably influenced by intercurrent influenza. In adolescence the relation sustained by influenza to pneumonia seems about the same as scarlet fever to desquamative nephritis in childhood. In what this tendency consists it is easy to understand. In the first place, there is the catarrhal affection of the whole upper respiratory apparatus which belongs to the influenza. Extension downward may easily occur. Secondly, the pneumococcus is present at nearly all times in the mouth, and all it requires for its development is exposure and reduction of the body temperature. Finally, we have a condition of toxic ptomaïnemia and groups of bacilli floating in the blood. The probability of their at times lodging in the pulmonary capillaries is suggested by the fact of Krouse, of Vienna, finding pulmonary abscess, and of Kundrat reporting gangrene. This of course may also be a stadium which has substituted itself for resolution in the gray hepatization of the ordinary pneumonia.

Induration of the lung has been seen by Kolisko. Pleuritis and empyema may occur with or independent of pneumonia. Levy has found the pneumococcus in pure culture in a sero-purulent exudate.

Tuberculosis as a sequel of influenza is well authenticated. I have myself seen many such cases, and I have further observed that the number of old tubercular patients applying for admission to the hospital during an influenza epidemic is markedly increased. That is to say, their condition is exaggerated by influenza, and they sometimes have hæmoptysis during the attack.

Embarrassment of the heart's action similar to that occurring in diphtheria has previously been referred to. It is often our chief danger signal and a demand for active stimulation. Rohring speaks of a remaining palpitation in 239 soldiers of which he had charge. Purulent pericarditis and endocarditis, leading to organic lesions, stenosis, and regurgitation are found in the literature. Krouse, of Vienna, tells of infectious phlebitis and localized passive discoloration of the skin, conditions speaking for bacterial embolism.

Complications referable to the nervous system comprise for the most part neuralgias, arthralgias, neuritis, paralyses, atrophies, and certain functional derangements of the cerebrum. Post-influenza neuralgia may not manifest itself for several days, or even weeks, but is severe and most obstinate to treatment. Either cranial or spinal nerves may be involved. The paralysis and atrophy may be due to neuritis, as was observed in case of the radial and median by Ruhemann.

The origin is central more often, probably, and has a toxic basis. Then Mendel's theory of intra-cranial capillary hemorrhage, as in post-diphtheritic paralysis, is to be considered.

Muscles of the ocular group, the palate, or of an extremity, as observed by Henoch, may be the seat of paralysis.

Professor Crego, of Niagara University, Buffalo, cites two cases of acute myelitis, and has seen many cases of insanity following influenza.

Leichtenstein detected punctate hemorrhages in the cord of a female patient who died of this disease. He has described eight cases of mono- and hemi-plegia, and speaks of an influenza apoplectica, the cases having impressed him as being due to cerebral embolism.

Isolated cases of aphasia, tetanic and epileptiform convulsions, and loss of consciousness, also hemianæsthesia, analgesia, tremor, a subsultus tendinum, and cases of inequalities of the pupils and nystagmus, are found in reviewing the records of past epidemics.

Epileptiform convulsions occurred where there was no organic brain lesion, microscopically, to be established—another point for a ptomaïne or toxine expending itself on the central nervous system. Organic lesions do occur, however. Hyperæmia of the meninges, actual meningitis, and brain abscess have been revealed by autopsy. In a case of suppuration in the antrum of Highmore, where

death occurred suddenly in coma, there was found an acute basilar meningitis.

Williamson saw a case of alopecia areata defining sharply the innervation of the supra-orbital and occipital nerves.

Long-standing nervous affections, hysteria, and neurasthenia, are made worse by intercurrent influenza, as a rule.

Tabes dorsalis, and the funicular scleroses tend to an exaggeration of their symptoms. The relation existing between influenza and psychical disturbances seems positively to be that of cause and effect, although up to the year 1790 there is nowhere mention of the fact to be found. Jutrosinski believes in the possibility of the excessive use of antifebrin and antipyrin; not only by the laity but also by physicians, as being accountable for some of the hysteria, melancholia, hypochondriasis, and delirium in influenza. Dementia, paranoia, delirium tremens, and progressive paralyses are other varieties of nervous complications which may be assumed.

The causative relation of influenza to affections of the nervous system may be briefly formulated as follows: 1. As a rule, it is only when a predisposition exists that psychical disturbances develop. 2. Psychical disturbances may show themselves at any stage of the disease, but are more liable to occur in the depression of the convalescence. 3. Any form of psychical disturbance may be assumed, although melancholia and the hypochondriases are the more common. 4. Both sexes are equally disposed. 5. The larger contingent of cases occur in middle life. 6. The prognosis is favorable, the course and duration transitory. 7. The effect of influenza on already developed psychical affections has been discussed pro and con, and is not as yet fully determined.

Complications on part of the eye in influenza are not uncommon; they comprise for the most part conjunctivitis, episcleritis, keratitis, and iritis. Konigstein has observed glaucoma, paralysis of accommodation, and optic neuritis with atrophy. Choroidal embolism with consecutive panophthalmitis, and cases of embolism of the arteria centralis retinæ are noted.

As nearly every other organ and function in the body may be implicated in influenza, so also do we find the ear partaking of complications. In the ear clinic of Vienna a great number of affections are seen referred to this troublesome disease.

Otitis media acuta and purulenta is the most frequent, and is sometimes combined with myringitis hemorrhagica bullosæ. Gruber has operated six times upon the mastoid cells for necroses and evacuation of pus resulting from influenza. Hubbell has operated four times in the past winter. Atkins speaks of a transitory initial hyperæsthesia of the sense of hearing.

In the middle ear inflammations a most rapid exudation takes place, sufficing in twelve hours to rupture the membrane, and necessitating therefore a prompt paracentesis.

With evacuation of the pus and relief of the tension, the pain subsides in the majority of instances; although with Politzer we learn of an obstinate intermittent otalgia continuing after the middle-ear inflammation has subsided. In the pus of an influenza otitis media, Weichselbaum has found his diplococcus, but of course it is nothing new to find this germ in any part where suppuration is present.

The otitis media of influenza should be regarded as a dangerous complication; not seldom it has led to sinus phlebitis and thrombosis, pyæmia, purulent meningitis, encephalitis, and death.

With regard to the relations of influenza to the female genital apparatus and its functions, there have been a number of observations made during the past epidemic, and the consensus of opinion is that menstruation in association with influenza becomes a dysmenorrhœa. There is exquisite tenderness on palpation over the uterus, the pain almost assumes a peritonitic character, and the case terminates in menorrhagia.

There is much of a tendency to metrorrhagia in patients with chronic metritis. Abortions are not uncommon, and were referred in ancient times to acute endometritis. Women in normal labor at term have pains of extreme intensity, but they are ineffectual.

Of 102 post-parturient women in the Frauen Clinic in Munich, at the time of the last spring epidemic, 64 contracted influenza. In those cases where the temperature was high the lochia became profuse and offensive. Anton has observed that just at the onset of the menstrual epoch females were especially liable to influenza. Herpes labialis oris occurs in twelve to twenty-five per cent. of cases, and is looked upon as a sort of welcome sign, as in pneumonia, where it is associated with resolution. Erythemas are very common. Hamilton reported a scarlatiniform eruption. Comby saw a roseola, in 5 cases out of 218, simulating typhoid spots. Urticaria was mentioned as early as 1709. Acute psoriasis has occurred, but was perhaps a coincidence. A case in Leyden's clinic recently presented erysipelas complicating influenza, or rather the two were associated in a post-parturient. Leyden thought the influenza was favorably influenced by the erysipelas occurring, and suggested its possibility as a factor in immunity, although immunity seems rather dependent upon some of Buchner's isolated defensive proteids formed by the animal metabolism and capable of destroying some of the microbes, or rendering inert their chemical products of these—phylaxines or some of the sub-classes.

As respects urelogia, we have the possibility of cystitis and acute hemorrhagic nephritis, such as Strumpel reports, to consider. With regard to surgery, we would be led by Verneuil's report to fear pyæmia when a wound exists in influenza. Verneuil has shown that wounds manifest a suppurative tendency, and that there is danger of constitutional septic infection. Healing will not progress and it is injudicious to operate when this disease is prevalent. Purulent accumulations in cavities—the pleura, pericardium, antrum and frontal sinuses, deep cutaneous and glandular abscesses, acute orchitis, and otitis with mastoiditis, are some of the surgical sequelæ. Park evacuated a litre of pus from a subfacial abscess of the thigh in a case of acute influenza. Operations involving the nasal, buccal, and respiratory tracts are contra-indicated during influenza, owing to the great liability to infection.

In summary, we have seen that influenza comprises an exceedingly extensive chapter in medicine. The symptomatology of the disease alone is by no means limited; then its array of complications and sequelæ, and its capability of markedly exaggerating and unfavorably influencing all chronic standing affections, especially those of the nervous system, make it a disease second to few others in clinical importance.

The long list of consequences addressing themselves to every system and nearly every organ in the body speaks volumes for our having to do here with a general septic infection, and not with a miasm, as the older writers thought. In fact, no argument is necessary any longer. We have the one absolute and convincing factor, the presence of bacteria floating in the blood and being disseminated through this medium to the remotest recesses of the body. Not even left a possibility for scepticism, as in case of diphtheria and tetanus, where the bacilli are found only at the point of inoculation, and the symptomic consequences have to be taken for granted as due to the germ's chemical products.

Here, I say, we have the bacilli in the blood and floating around in aggregated masses. How easy it is then to understand that embolism may occur, and indeed septic embolism, which means, in the vast majority of instances, abscess. The influenza bacillus has been found in the sputum, in the blood and the tissues, it only remains now for some individual to establish its presence in the embolic apoplexies, in the inflammations and suppurative conditions which play such an important rôle in the complications of the disease. I have no doubt but that Weichselbaum saw the germ a number of times in his diligent searches of the

exudates. But the recognition of an unknown thing is always difficult. It further remains now for some individual to immortalize himself by producing an immunity for influenza through proper attention and re-inoculation of the virus, as Jenner has done for small pox, Pasteur for hydrophobia and chicken cholera, and partially for anthrax, and as Koch is trying to do for tuberculosis, and Emmerich for pneumonia. This then will constitute the therapy of which it now remains for us to say a few words.

Without the immunity, we have to give prophylaxis the next place in the rank. And with absolute prophylaxis we would not need any immunity, there would be no disease. As in case of tuberculosis, we could theoretically stamp it out. As we increase in perfection in prophylaxis, and instil into the laity the importance of its principles, to a corresponding extent will our need for remedies diminish. Future therapy will consist in prophylaxis chiefly. Without infection there are none of the consequences of infection. Formerly it was antisepsis. Now it is asepsis. They sustain to one another the ratio of prophylaxis to therapy. One admits the presence of infection and then tries to remedy it, the other precludes the possibility of infection, and is certainly the more rational. In the treatment of influenza, then, we place prophylaxis in the foreground; and in what does it consist? 1. Simply in the proper precautions regarding avoidance of exposure when an epidemic is current, and, 2, the disinfection of the bacteria laden sputum.

Cuspidores containing carbolic-acid water, such as are used in the Koch Institute, should be universally employed. How many tubercle, influenza, and other forms of bacilli could be kept out of the atmosphere we are inhaling if they were held down by maintaining the expectoration moist.

When influenza occurs, of course we must treat it, and we treat it in the way we do most other diseases, viz., symptomatically. Unfortunately we have no specific, and probably will not have till it comes through the channels of immune bacterial products As for prophylactic remedies, quinine, the principal one in question, has been given a negative decision. But it is a good tonic, antiseptic, and antipyretic, and therefore a good all-around remedy. Exalgine, phenacetine, and antifebrin have been extensively used. Benzoate of soda is good.

Stimulants may receive urgent indication. The mouth and nostrils should be cleansed antiseptically as a further prophylactic. Inhalations of icthyol are valuable. Remaining to be mentioned are codeine, salol, naphthol, and iodide of potassium, all of which have their indications and their adherents. The complications are treated according to what they are and how they occur.

610 Main Street, Buffalo, N. Y.

Typhoid Fever in the Boston City Hospital.—Dr. A. L. Mason, as a result of the study of six hundred and seventy-six cases of typhoid fever admitted into the Boston City Hospital in 1890 and 1891, comes to the following conclusions (*Boston Medical and Surgical Journal*): 1. That in the Boston City Hospital the mortality in typhoid fever from patients admitted moribund and with grave complications, is four per cent. 2. That at least three per cent more die from intestinal perforation and hemorrhage. 3. That little diminution in the mortality from these causes can be expected under any mode of treatment. 4. That the mortality from renal, pulmonary, and circulatory disturbances, from diarrhœa and pyrexial exhaustion, is about 3 5 per cent. 5. That, excluding deaths from intestinal perforation and hemorrhage, the mortality among females is 3.4 per cent greater than among males. 6. That a diminution of two per cent. in the general mortality might be expected from the systematic use of cold baths, the reduction being largely in females. 7. That favorable results followed the trial of intestinal antiseptics, but that relapses were not prevented thereby, and that a much wider experience is necessary to determine their value.

DEMENTIA EPILEPTICA—IMPROVEMENT OF THIS FORM OF MENTAL IMPAIRMENT FOLLOWING LINEAR CRANIOTOMY.

By HUGO ENGEL, A.M., M.D.,

CONSULTANT IN NERVOUS DISEASES AND IN CHARGE OF THE INFIRMARY FOR EPILEPTICS AT ST. JOSEPH'S HOSPITAL, PHILADELPHIA, PA., ETC.

Linear craniotomy, a suitable name proposed by Keen,[1] and decidedly better and more correct than craniectomy, a term given to it by Lannelongue,[2] is an operation by which pieces of the skull are resected to give to the brain more space for expansion. In trephining by the aid of the instrument, we saw out a circular piece of bone, a button. This operation to-day is done mostly for the purpose of enabling the operator to introduce other instruments underneath the skull to raise such parts of the fractured bone as have become depressed, and give rise by their presence to symptoms, either of cerebral irritation, or of compression. Then this operation is also performed in cases of cerebral hemorrhage, when circumstances having made possible the exact location of the clot, the coagulated blood producing compression of the brain, or giving rise to convulsive seizures, or to other morbid phenomena, is to be removed, and found beneath the opening. Finally, trephining proper has been practised for the cure of epilepsy, and it may interest the reader to know that there is evidence of trephining having been performed in prehistoric times, and of its probably being the oldest operation ever attempted on the human body.

The ancients gave to epilepsy the name of morbus sacer, and while the disease, therefore, as well as the person afflicted with this dreadful malady, were looked upon by them as sacred (as our Indians to-day treat with deference any demented individual), this sanctity became of a still higher order when trephining had been done on such a patient with the view of curing the "falling sickness."[3] Broca has adduced proof that trephining was practised for the same purpose in prehistoric times,[4] and there is no doubt that our forefathers of the stone age were acquainted with it.

Probably, as von Bergmann[5] sagely remarks, because of the uniform failure of the operation to cure, trephining for epilepsy was afterward abandoned. The period of the gradual withdrawal of the operation began with Desault, and ended with Dieffenbach,[6] after which, until the most recent times, trephining for epilepsy was undertaken only when some proof of an injury to the skull, as a cicatrix, etc., could be discovered in the cranium of the patient. As we see from Seydel's table,[7] even since the antiseptic era has domineered, but twenty-nine cases have been reported where trephining was resorted to for the sole purpose of curing epilepsy.

Since Horsley has drawn our attention to the fact that the removal of a button of bone is not sufficient, but that, especially in older cases, a part of the underlying cerebral cortex must also be destroyed to obtain success, the operation has received a fresh impetus again, and a new field has been opened to it.

Originally, while perhaps desiring simply to stop the fits of an epileptic, and finding instead the mental faculties to receive the benefit of this operation, the latter has also been advised as a means for improving mental disturbances. To-day we do not stop here, but to the trephining we add resection of a piece of the skull, as will soon be explained more in detail.

While one-half of all epileptics evince not only no deterioration of the intellect, but are remarkably bright and

[6] Also quoted in v. Bergmann's work on the Surgical Treatment of Brain Diseases.

[7] Seydel: Antiseptik und Trepanation. München, 1886.

in vigorous health,[1] many of these unfortunates are characterized by a condition of the psychical sphere bordering on imbecility, and between simple impairment of memory and sluggishness of perception on the one hand, and complete idiocy with or without maniacal outbreaks on the other, every variety of mental disturbance may be met with as a complication of epilepsy, or as an apparent sequela of the same.

That the two—epileptic seizures and impairment of the intellect—are by no means synonyms, and that they do not stand to each other in the relation of cause and effect, not only the many patients prove who are subject to convulsions while possessing great perceptive powers and a quick intellect, but the results of operations also demonstrate, which, though often securing the mental improvement, yet secure no relief to the fits. We may say, however, generally speaking, that the same morbid state that caused the convulsions also is responsible for the mental shortcomings of the patient.

In children a disease is met with which has thus far been classed with epilepsy, in which the mental impairment and the convulsions begin at one and the same time, always suddenly, and both the disturbance of the intellect and the convulsive seizures run an independent course; one may be cured while the other continues unabated.

These children, during the first years of their lives, give every promise of becoming useful members of the human society. They often prove very bright and vivacious, and up to their third, fourth to seventh year, and, rarely, even up to the fourteenth, no warning premonitory sign indicates what is to happen later.

Generally, in the midst of apparent health, such a child is seized with convulsions which, though from the start of the character of those of haut mal, yet gradually increase in severity and frequency, and are specially distinguished from other attacks of epilepsia gravior by the intense force with which the victim of this malady is thrown down. Thus, for instance, while standing or walking, as if some great power had grasped him, such a patient is hurled to the ground with a tremendous force; or, while sitting on a chair near a table his head is thrown against the latter as if shot from a cannon. These attacks set in lightning like, and in this variety of epilepsy they are further characterized by their generally beginning in some group of muscles, after which they attack the whole muscular system, and by the greater tonicity of the spasms, the rigid element decidedly preponderating. These patients never seem to have an aura, nor does the disease ever begin as petit mal, the seizures from the start having the character of those of epilepsia gravior.

The rapidity with which the attacks soon follow each other also specially distinguishes the malady in question; often what the French term *états de mal* develop, and the disease then resembles the convulsions of cerebral tumor, especially of the luëtic kind. While new-growths were not met with in my cases of epileptic dementia, the altered state of the cranium really causes the latter to act like a neoplasm upon the soft tissues underneath, as will be explained below.

In later life the victims of dementia epileptica, if they do not die earlier, or if no operation comes to their relief, are transferred to our institutions for the imbecile and the idiotic, and there end their lives.

Local palsies and hemiplegia may occasionally accompany this type of grand mal, or after the convulsions have been in existence for a while—from a few weeks to a year or more—paralysis may seize those parts in which the spasm begins, or in which the convulsive movements are the strongest and which remain rigid the longest. In no case does the palsy precede the other symptoms, thus pointing to a valuable sign in the differential diagnosis between uncomplicated infantile paralysis and epileptic dementia at its commencement; for after a certain period has elapsed, and when the mental impairment has clearly developed in the epileptic disease, an error of that kind is not apt to occur.

While, therefore, in some respects this epilepsy resembles somewhat the Jacksonian variety, its most important symptom is absent in the latter, viz., the impairment of the mental faculties. Although at the commencement but slight, the mental disturbance yet makes rapid progress, and is by no means dependent upon the convulsions; for, however slow the increase in severity and frequency of the fits may be, the intellect deteriorates rapidly, and if we succeed in improving the intellect and in completely removing its cause, and with it the imbecility, etc., this one-sided amelioration does not bring about the cessation of the convulsions, and has at the most but a slight influence on the severity of the latter. Also, if under a treatment calculated to lessen the reflex excitability of the convulsive centre, we obtain a cessation of the epileptic seizures, this usually transient improvement does not produce the slightest change in the mental sphere, the impairment there remaining exactly the same, or continuing its steady progress toward worse. And in not a few cases any diminution in the fits (either severity or frequency) leads to serious maniacal outbreaks and greater imbecility—an aggravation which ceases when the convulsive attacks are once more allowed full play.

There are some points of difference between the mental disturbance distinguishing the disease in question and that due to any other cause. To be sure, a great many conditions influence the mental affection met with in each case. Previous education and surroundings, natural tendencies, the rapidity or slowness with which the pathogenic element develops, its exact seat—all contribute their share in determining the result. But the peculiarities which specially characterize the form of mental impairment complicating the grand mal here referred to, are the following:

What first strikes us is the evident retarded mental development without any interference in the growth of the physical body. Usually imbecile and idiotic children are also stunted in their physical systems; they often are cripples or have some kind of malformation. Such never occurs here, unless as an accidental complication with no connection whatever with the malady spoken of; on the contrary, the physical health is excellent and all animal functions are well performed. Looking at such an unfortunate child, we see at once that the psychical sphere alone suffers.

The next distinguishing point is the peculiarity of the mental aberration. These patients sulk; the look of their eyes, the movements of the muscles concerned in expression are very vulgar; the speech of these children is heavy, and they are given to obscene language; while the whole apparatus ruled over by the speech-centre is evidently not disturbed. They talk correctly, but in a grumbling, sulking manner; they always are morose, suspicious, and vicious. Their countenance does not show the facies epileptica, but it makes the impression of the face of a shy, half-tamed animal constantly in fear of the lash. They understand plain questions asked of them and answer them rightly, especially when they concern the patients themselves, but the replies are thrown out in a slow, heavy, unwilling manner, which no word can characterize better than: sulking. They glance at you from the corner of their eyes, which otherwise usually stare at the floor, and I have never seen a case where the look had not some sign of hatred in it.

The mental impairment attacks the emotional sphere; the moral sense of these children is obtunded, and their whole character is described best by its most distinguishing quality: vicious.

One point shared by all is this: upon careful investigation we find that the mental development, having proceeded undisturbedly up to a certain time, had been suddenly arrested; remained at that stage, then travelled backward a little; while human passions, vices, and

[1] Nothnagel: Article on Epilepsy in Ziemssen's Cyclopædia, vol. xiv.

immoral ideas and practices from that moment on were uncurbed and became more and more licentious.

We have here the important differential diagnosis between microcephalus and epileptic dementia. The microcephal enters the world as such; it is born with him; in dementia epileptica the mental impairment begins at a certain age, simultaneously with the convulsions; at the same time the moral inhibitory centres are weakened from that time on. The older the child, when the epileptic malady begins, the less apparent are the mental shortcomings.

Finally, all these cases are especially prone to maniacal outbreaks, which increase in severity with the duration of the disease, as if the mental inhibition becomes weaker, the longer the disease lasts. There are many cases of epilepsy where the intelligence in the intervals between the seizures is not disturbed, but where, either before or after the attack, acute mania develops, which occasionally seems even to take the place of the convulsive seizures. These cases have no connection with epileptic dementia. When such patients are brought under the influence of the bromides and the fits cease, the maniacal outbreaks generally become only severer. We are now approaching epileptic insanity—a disease greatly differing from what I term epileptic dementia. The so-called epileptoid states, during which a patient, driven by an irresistible force within him which he cannot control, commits the gravest crimes, or in milder cases becomes a dipsomaniac, belong to the same category as insanity, but are met with only in adults; while from the very nature of epileptic dementia that disease can commence only in children, as we will soon explain.

The violence in the disease in question also comes on suddenly, but something provokes it. It is simply here an evidence of unbridled passion; a rage, into which the patient works himself on the slightest provocation. If the disease progresses to adult age, as once before mentioned, the patients must be cared for in asylums, as their violence becomes dangerous, while their imbecility makes them helpless; for the longer the duration of the complaint, the more the original normal mental development seems to decay.

We will now consider the cause of epileptic dementia. In every instance the disease is due to an abnormal formation of morbid bone-structure. In no case have I found the skull to consist of normal bone; in all the organic element is wanting, either completely or partly, and the earthy matter predominates. In most cases there are no outer and inner laminæ, nor any distinct diploic structure; the bone resembles mortar to which much chalky substance has been added, and of the smooth, hard, enamel-like surface, presented especially in the frontal and temporal regions by healthy skulls, not a trace can be detected in the cases referred to here. This abnormal composition of the bones of the skull is always associated with a similar condition of the teeth, while the rest of the skeleton gives no evidence of such a formation in the living being. But the morbid state of the different bones of the cranium evidently precedes everything else abnormal in the skull; *i.e.*, as soon as the change in the structure has occurred the next step begins: there is too much bone-formation, and this in its turn leads to what causes the disturbance in the brain, too early and too solid closure of the fontanels and of all the sutures. I do not believe that the last few steps in the development of the disease spoken of can ever set in, as long as the structure of the bone is normal. Thus far I have not yet met with a proof to the contrary, and although I have seen some early cases, wherever an opening was made in the skull the abnormal structure was apparent; and so uniform was this condition all over the cranium—as far as inspected—that considering the short duration of the brain disease, the pathological state of the bone-structure must have preceded all the rest.

It is the final outcome of this state, viz., the too early solid condition of the cranium, setting in at a time when the brain needs room for expansion most urgently, which is responsible for the malady called by me dementia epileptica, and the only remedy for which is offered us by linear craniotomy. When correctly performed, and in well-selected cases, this operation invariably leads to great improvement of the mental disturbance—in fact to a cure; while regarding the epileptic seizures, it only diminishes them—generally to a great extent—both in frequency and severity.

To obtain such a result we must be certain of a correct diagnosis. This, to recapitulate, necessitates the presence of the following conditions:

1. In a child with normal mental development and physically vigorous, up to a certain age, no premonitory symptom foretells the later disease.

2. Suddenly the child is seized with convulsions, which from the very start have the character of attacks of haut mal, but are distinguished by their greater violence, longer duration, greater frequency, and by the predomination of the tonic element.

3. Simultaneously with the convulsions there begins the mental impairment, which is characterized by the patient remaining intellectually forever in *statu quo*, and by the absence of all proper inhibition or of mental control over the passions; so that finally, like in an animal, all ideas of morality are extinguished, while the passions have full play, so that uncontrollable outbreaks of violent temper are frequent.

4. The history of the case and an inspection of the cranium betray the cause; abnormal and augmented bone-formation, which had led to too early and too solid bony union of the bones of the skull.

5. Abnormal shape of the cranium, whose dimensions are narrower, and which presents depressions and flattening where the shape should be vaulted.

6. Utter absence of other physical malformation, unless as accidental complications.

The diagnosis having been established, improvement rapid, and often miraculous, following linear craniotomy, may be guaranteed. Here the point is to perform the operation exactly at the seat of the trouble, which will generally be found within an area whose centre is the junction of the coronary and sagittal sutures, extending from there especially backward and downward, affecting mainly the upper and anterior part of the squamous portion of the temporal and the anterior third of the parietal bone, and the upper part of the frontal bone.

Besides inspection, special symptoms may here guide us. In one case, for instance, from the very commencement the vocabulatory previously at the disposal of the child had become diminished, and all through the whole duration of the disease the boy seemed to have trouble in finding correct expressions for what he wished to say, and the learning of new words was difficult. Here linear craniotomy was performed mainly over the region of Broca's convolution, and the result was astonishing, so great was the improvement following the operation.

In another case the convulsions always began with a contraction of the levator anguli oris et alæ nasi on the right side, and when the child—also a boy—talked, some paresis around the right corner of the mouth was plainly noticeable. Here bone was resected over the lower end of the fissure of Rolando and the cure was complete.

As in most cases bone must be removed on both sides of the skull, it is preferable to operate on one side at the time, as all the cases in which both sides were operated at the same time, and especially when the intervening bridge also was resected, ended in death; while the operation, when divided, seems to be free from danger.

The operation itself is simple. The boundaries of the piece of bone to be removed having been determined on the shaved and previously disinfected scalp, and landmarks having been bored with a drill through the scalp in the bone underneath, a sufficient portion of the scalp is then dissected off, including the periost. The two opposite ends of the piece marked are then removed by the

aid of the trephine, selecting, if we wish to resect a piece one inch wide, a one-inch trephine, etc. The buttons having been taken out, the intervening bone is sawed out, for, in the opinion of Sahli, the sudden death which has occasionally occurred from the operation, is due to the concussion brought about by the use of the chisel and hammer.

Any uneven edges or sharp corners may be rounded, or in case still more space is desired, the removal of more bone can be easily accomplished by the use of Horsley's bone-forceps, improved by Keen.

To be sure, strict asepsis is a *sine qua non*. I have performed linear craniotomy a number of times, and in every case where the dura had not to be opened obtained closure of the wound within from ten to twenty days, the size of the bone resected and that of the portion of the scalp to be dissected off, and the age of the patient, determining, cæteris paribus, the duration of convalescence. As a rule, the younger the patient the quicker heals the wound.

I believe, if we succeed in determining the exact locality of the irritating focus, so that we are certain of the part of the cortex to be removed, and destroy the latter, we may also cure the fits. This, however, though written down easily enough, is difficult to find out. In the one case above referred to it took nearly a year's observation, and needed the watching of the little patient in about twenty seizures, before I was sure that the convulsions always attacked first the *levator anguli oris, alæque nasi dexter*. After the removal of the bone the dura was laid bare near the lower part of the fissure of Rolando, and the exact centre determined with the faradic current. It was interesting to observe how, the moment the right spot had been touched, a spasm seized that part of the face and the right arm. The cortex for the depth of about one-sixteenth of an inch looked darker, and was cut away that far. The first few days a few twitches were noticed in the lower part of the right face, after that all convulsive movements ceased forever. Here the irritation of the centre of the levator muscle must have produced a reflex action through the brachial plexus of nerves.

In another similar case, the right hand always became clinched first. Here also the centre was removed by me, but probably not deep enough. The operation was followed by paralysis of the hand and wrist for two weeks, when the palsy left, but the boy, aged twelve, still has occasionally slight twitchings in the right hand extending up the right forearm, without, however, there being any unconsciousness or active spasms, and the twitching itself seems to become milder and to appear less frequently. The most peculiar point here is, that the boy since has become left-handed, the right arm having also lost in power, and I believe, not only from want of use.

This subject, however, does not belong to the domain of this article and I must refer the reader to the most recent literature on the subject besides the quotations already referred to.[1]

How the epileptic dementia develops, by what physiological and pathological and psychological process the impediment offered by the bone causes not only a standstill of further mental development, but also the cessation of all mental control—inhibition—over passions, and how these disturbances can disappear immediately after the removal of the obstacle, is a very interesting study, but a subject whose consideration must be left to another time.

LEGISLATION ON MEDICAL AND HEALTH MATTERS IN THE VARIOUS STATES IN 1891.

By HENRY A. RILEY, A.B., LL.B.,

NEW YORK.

(Continued from p. 516.)

Oregon, Pennsylvania, South Carolina, South Dakota, Tennessee, Texas, Washington, West Virginia, Wisconsin, and Wyoming.—The State of Oregon passed two general statutes for the regulation of medicine and pharmacy.

The first provided that the State Board of Examiners should issue certificates to all persons who furnish satisfactory proof of having received diplomas or licenses from legally chartered medical institutions in good standing, of whatever school or system of medicine, and directed that the certificates should be of three kinds: the first for those holding diplomas or licenses, the second for candidates examined by the Board, and the third for those in practice and who had registered according to the terms of the law of 1889. Every person who has registered under this law was required to present to the State Board a certificate to that effect from the County Clerk, and another certificate would then be issued to him entitling him to practise medicine and surgery.

The law gave a hint to the Board not to be too hard on the applicant for a license, by providing that all examinations made of persons not graduates or licentiates were to be made by the Board, in whole or in part, in writing, and were to be of an elementary and practical character, but sufficiently strict to test the qualifications of the candidate as a practitioner. The fee for an examination was $10.

The Pharmacy law was modelled a good deal after those in force in other States, and established a State Board consisting of five persons. Every person doing business as a pharmacist must be registered, and in order to obtain a certificate he must be either a graduate or a licentiate, or a person in active practice at the time of the passage of the act. Those persons in active practice must furnish proof of such fact within three months.

Every registered pharmacist, apothecary, and owner of a pharmacy is held responsible for the quality of drugs or poisons, except those sold in the original packages of manufacture and those known as proprietary and patent medicines.

Any licensed practitioner of medicine is not subject to the law, but may furnish patients with any articles he may deem proper, and the law does not apply to wholesale dealers or manufacturers of patent medicines. The protecting shield of the law was thrown over the singing bird, by an act forbidding the killing or selling of any nightingale, skylark, black thrush, linnet, goldfinch, bullfinch, black starling, grossbeak, mocking-bird, etc., these being "the species of German and American singing birds introduced and about to be introduced into this State from Germany and the Eastern States by an association styled, viz., "Association for the Introduction of Useful Singing Birds into Oregon," of which Mr. Frank Dekum, of Portland, is President.

A law was passed directing the names of all deaf, mute, or blind children between the ages of six and four-

Idem: American Journal of the Medical Sciences, December, 1891. Idem: ibidem, September, 1891. Idem et ibidem, October and November, 1888. Idem: Transactions of the New York Medical Association, vol. vii.

teen, to be reported by the clerks of school districts to the county school superintendents. Such children, if not being educated by their parents, were to be sent to the State institutions.

The State veterinarian was authorized to employ local inspectors to ascertain the existence of contagious diseases, and to establish quarantine. The salary of the office was fixed at $1,500 and expenses.

Pennsylvania.—Pennsylvania, like New York, has found it necessary to make greatly enlarged provision for the multitudes of the insane, and enacted a law directing the erection of an Asylum for the Chronic Insane.

A board of five commissioners was authorized to be appointed by the Governor to select a site and erect the buildings. The proviso was made that the site should be convenient to the other asylums for the insane, and must contain not less than five hundred acres of land. The cost of the land and buildings was not to exceed $500,000.

Another commission of five persons was authorized to select a site for a quarantine station on the Delaware River, remote from the centres of population. The commission was also directed to inquire into the feasibility of a joint quarantine for the protection of all parts of the Delaware River and Bay, to be controlled by the several States bordering thereon.

An elaborate law was enacted for the proper management and working of coal mines, after having been considered and approved by a committee of nine inspectors, mine owners and practical miners.

The anthracite coal fields were divided into eight inspection districts, with an inspector at the head of each who was to be chosen by a Board of five examiners, three of whom were to be practical coal miners and two reputable mining engineers.

The inspectors must see that all necessary precautions for safety are taken at the mines, and must visit the scene of every accident and attend all inquests on the bodies of persons killed at the mines.

Mine owners were directed to provide at the collieries an ambulance with two stretchers, for the purpose of conveying to his home or an hospital, any person injured. The ambulance must be provided with easy springs, bedding, spring mattresses, etc.

Two laws relating to cemeteries were passed, and might profitably be enacted in other States. One provided that property could be left for the care and maintenance of graves, monuments, etc., and that such bequests would not be void as violating the statute against perpetuities. The other allowed incorporated cemetery companies to accept by deed or will, devises or bequests in trust for the care of family burial lots, vaults, or graves, provided the companies obtained from the Court of Common Pleas of the County approval of the form of investment of the principal sums.

The Pittsburg Crematory is said to do a thriving business, and the Legislature assumed control over it by providing that, before any cremation was allowable, a permit should be obtained from the Board of Health. Before such a permit could be given the physician or coroner must file a written certificate giving the facts of death and the usual information.

The pharmacy law was amended so as to permit the legal representatives of a deceased registered pharmacist to carry on the business under the charge of a qualified and registered assistant.

The Board of Public Charities is accustomed to pass on the applications of public or semi-public institutions for appropriations from the public treasury, but a good many bills seem to have been introduced which gave sums in excess of those recommended by the Board, and in some cases where the Board had refused to make a recommendation at all. Many of these bills were vetoed by Governor Pattison.

Quite a large number of appropriations were made for small hospitals at different cities and towns in the State, on condition that land and money were contributed by private citizens. Such hospitals were authorized at Chester, Connellsville, New Castle, Pottstown, Carbondale, Pittston, etc.

South Carolina.—This State has taken a step backward in its medical practice legislation. The law of 1888 provided for the appointment of a Board of Examiners, consisting of five physicians, to whom should be presented all diplomas for examination; and the Board was authorized, at their discretion, either to issue a license thereon, or to examine the applicant further. The law was satisfactory to the profession and prevented the practice of medicine by quacks. In 1891, the Legislature, in which, it is said, were two men who had been rejected by the State Board, passed a law providing that all physicians, before engaging in the practice of medicine, should submit their diplomas to a Board consisting of three reputable physicians in each county, said Board to be appointed by the Governor upon the recommendation of the medical society of the county.

The law does not refer to the Medical Practice law of 1888, but is considered by the Secretary of the State Board as practically making that statute inoperative, and he states that the Board is not now exercising its functions. Another law was passed which will not be viewed with favor by physicians. By a statute passed in 1885, any physician or surgeon summoned, either by the State or the defendant to testify as an expert in cases before the Court of General Sessions, was to receive $10 in addition to the fees given other witnesses. An amendment passed at the last session reduced the compensation to $5.

Another law forbade the transportation within the State of any horse, mule, or ass suffering with the glanders. If any person violated this provision and did not have a clean bill of health from a veterinary surgeon, that the animal was sound when brought into the State, he was liable to punishment for a misdemeanor and must pay all damages incurred.

South Dakota.—In this State a comprehensive law was enacted, providing for a State Board of Health which, in addition to the ordinary duties of such a Board, was to supervise the admission to medical practice. The Board was to consist of three physicians in good standing, to be appointed by the Governor.

The Board was given power to make and enforce rules and regulations to prevent the spread of contagious, infectious, and malarious diseases among persons or domestic animals, to establish quarantine when necessary, and take any action required for the preservation of the public health. The general executive powers of the Board were to be exercised by a Superintendent of Public Health, who should receive compensation at the rate of $5 per day, and mileage of five cents. The Board was authorized to appoint two lawful physicians in each county, in connection with the State's Attorney, to be a County Board of Health. The County Boards were to be under the supervision of the State Board, and had power to enforce their regulations.

The provisions of the Medical Practice law are mainly as follows: No person is allowed to practise who is not a graduate of a lawful medical college, or who is an habitual drunkard, or a man of bad moral character.

If the applicant presents a proper diploma to the Superintendent of Public Health he was to receive a license, which was to be recorded in the office of the Register of Deeds of the county where he resides. Any person practising without complying with the law is guilty of a misdemeanor, and practising medicine within the meaning of the law means those who shall profess publicly to be physicians, and to prescribe for the sick, or who append to their names the letters M.D.; but this section does not apply to students who prescribe under the supervision of their preceptors, nor to commissioned surgeons of the United States Army and Navy, and does not prevent gratuitous services in cases of emergency.

It was declared to be a misdemeanor to fail to report to the County Health Superintendent the existence of contagious or infectious disease, either among persons or animals.

The law was further stated not to apply to those persons in the lawful practice of medicine, surgery, or obstetrics at the time of the passage of the act.

Tennessee.—In this State there were some amendments to the Medical Practice law which will be of interest. The right to practise by the law of 1889, was made dependent upon the registration in the office of the County Clerk of a certifice issued by the State Board of Examiners, and based either upon the diploma of a college in good standing or an examination by the Board.

Persons in actual practice were required to register their certificates within six months, but this period was extended by amendment to July 1, 1891.

The diploma referred to in the law must be issued by "some medical college in good standing, and said Board shall recognize any college that is recognized by the National Medical Association." This provision was changed so as to make the State Board of Examiners the judge of the "good standing" of the medical college, instead of the National Medical Association.

The 1889 law provided that any person who should practise medicine or surgery without the certificate of the Board of Examiners should be liable to a fine of $25 for the first offence, and $200 for each subsequent offence. The violation was made a misdemeanor in 1891, but the penalty was reduced to $10 for the first offence, and $25 for subsequent offences.

Itinerant physicians and vendors of drugs, ointments or other nostrums, or appliances for the treatment of diseases or injuries, were forbidden to carry on their business, under penalty of a fine of not less than $100 and not more than $400.

A general law regulating the practice of dentistry was passed in Tennessee. It was declared to be unlawful to practise dentistry or dental surgery unless the person held a diploma from some reputable dental college, school, or university department duly authorized in this State or some other State, where there was annually delivered, at the time of issuing the diploma, a full course of lectures and instruction in dentistry and dental surgery.

A Board of Examiners consisting of six practising dentists of acknowledged ability was authorized, and powers given them to issue certificates and decide upon the validity of diplomas. The Board was to keep a record of the names and residences of all persons entitled to practise, and those in active practice were directed to register within six months, upon which a certificate permitting the holder to practise should be issued. The compensation of members of the Board was fixed at $5 per day when actively employed, and expenses, all of which was to be paid out of the fees collected. The charge for a certificate without examination was $1, and with an examination, $5. Any person practising without complying with the law was guilty of a misdemeanor, and liable to a fine of not less than $25 and not more than $300.

The State decided to go into the pension business, and a law was passed for the benefit of Confederate soldiers, providing that a total disability, such as the loss of both arms, both legs, or both eyes should entitle a veteran to a pension of $25 per month. Partial disability, such as the loss of one leg and one arm, was to be compensated by the payment of $10 per month, and the loss of one leg or one arm by the payment of $8 33 per month.

It was declared to be a misdemeanor to give, sell, or furnish cigarettes or cigarette paper to any minor, under penalty of a fine of $50.

Any county with a population of 40,000 and upward was authorized to erect an asylum for the insane, the poor, the afflicted, and inebriates. The County Court was to appoint a building commission of six members, and the whole matter was to be under the control and direction of the court. A board of commissioners of five persons was to have the management of each institution when completed, and a superintendent was to be appointed who should be a "skilled physician of unblemished character, of enlightened and thorough professional education, of prompt business habits, and of humane and kind disposition. He shall be married, and with his family shall reside constantly on the premises."

Texas.—A law was passed in this State forbidding pugilistic encounters, or fights between a man and a bull or other animal, if bets were made or an admission fee charged. The offence was declared to be a felony, and the punishment a fine varying from $500 to $1,000, and imprisonment for a period from sixty days to one year.

A pugilistic encounter was defined to be any voluntary fight with or without gloves between two men or more, for money, prizes, or other things of value, and upon which money was wagered.

A paragraph was appended to the law as follows: "Whereas there is now no law prohibiting prize-fighting, and the offence is becoming of common practice, therefore the requirement of several days' reading be suspended."

An important health and quarantine law was passed, bearing mainly upon the yellow fever scourge. The Governor was authorized to issue a proclamation whenever in his judgment it was necessary, declaring quarantine on the coast or elsewhere, and for such period as the safety and security of the people required.

The Governor was to nominate and the Senate confirm the appointment of a Health Officer, who should be selected from the most skilful physicians of Texas, and who should from previous and active practice be familiar with yellow fever, and pledged to the improvement of both quarantine and sanitation.

The local health laws, when not in conflict with the regulations of the Health Officer, were declared to be in full force.

In case of quarantine the Health Officer must furnish shelter and subsistence to persons detained, and provide for their protection and comfort.

Vessels arriving from infected ports without a clean bill of health, were to be taken possession of by the Health Officer until all fines were paid or the vessels replevied by law.

It was declared to be the duty of every County Judge to select one physician of high character and recognized ability, who should be known as the County Physician.

It was the duty of the County Physician to maintain local quarantine, to enforce the rules of the State Health Officer, and to report to him all the facts concerning epidemics and their statistics. The salary of the State Health Officer was fixed at $10 per day and expenses, and that of the County Physician was to be fixed by the respective counties.

A law was passed raising the age of consent in cases of rape from ten years to twelve.

Washington.—In this State the principal laws of general interest were those relating to anatomical material for medical instruction, the regulation of pharmacy, and the establishment of a State Board of Health. The first declares that any physician, surgeon, or medical student may obtain human dead bodies for purposes of anatomical inquiry or instruction, and further directs all sheriffs, coroners, keepers of county poor-houses, public hospitals, county jails, and State prisons, to surrender the dead bodies of such persons as are required to be buried at public expense, to any physician or surgeon, to be by him used for the advancement of anatomical science, preference being given to the medical schools of Washington for their use in the instruction of medical students.

If such persons during their last sickness request to be buried, or if within forty-eight hours the body is claimed by some relative or friend, it must be buried.

The seemingly free permission for any physician to obtain a cadaver is qualified very decidedly by other pro-

visions. Every physician, before receiving a dead body, must give a certificate to the Board or official surrendering the same, from the Medical Society of the county where he resides, to the effect that he is a proper person to receive such a dead body. He must also give a bond with two sureties that the body will be used only for the promotion of anatomical science, and in such a way as not to shock public feeling. Any violation of the provisions of the law is punishable by a fine of $500.

The pharmacy law requires all pharmacists to be either graduates, licentiates, or already engaged in business. Four years' experience is required of a graduate, and three years of a licentiate.

The Board consists of five persons who shall be appointed by the Governor upon the recommendation of the State Pharmaceutical Association, which is to select fifteen names to be presented to the Governor.

Persons who are now engaged in business must become registered within sixty days.

All other persons must be examined by the Board. The proprietor of every drug store must keep a registry book for recording the sales of all poisons, and the name and address of the purchaser is to be given, and the amount asked for and the purpose stated by him.

All pharmacists are to be held liable for the quality of all drugs and chemicals except those in the original manufacturers' packages and patent medicines. The adulteration of any medicinal substance is punishable by a fine of $500. Any person compounding prescriptions after sixty days, who is not a registered pharmacist, is liable to a fine of $50. Physicians in regular practice, and manufacturers of patent medicines, are not subject to the law. The State Board of Health and Bureau of Vital Statistics was organized with five members, and general supervision given to it over health and life, with power to make rules and regulations and conduct such sanitary investigations as may be necessary. A State system of registration of births and deaths was authorized, under the charge of the Secretary of the Board.

The different county auditors were directed to keep a record of births and deaths in their counties, and it was declared to be the duty of all physicians, accoucheurs, and midwives to report such facts within thirty days.

When no physician was in attendance the cases were to be reported by the parents or householder.

A registry of marriages was also to be kept. It was the duty of the Board to examine into and report upon fatal and contagious diseases among domestic animals.

The salary of the Secretary was placed at $1,200 and $5,000 appropriated for all expenses.

West Virginia.—The legislation in this State was not important. The number of persons in a coroner's jury was reduced from twelve to six, and the coroner was ordered not to hold inquests unless he thought there was good cause to believe the death to occur through some unlawful act, except when a request was made by the prosecuting attorney.

The Governor was authorized to accept the regulations of the Bureau of Animal Industry, established by Congress for the prevention and suppression of pleuro-pneumonia and other contagious diseases among cattle, and the stoppage of any export of diseased cattle.

All expenses of quarantine and condemnation of animals was, however, to be paid by the United States.

A law was passed giving the maintenance and care of lunatics to the various County Jailors, and allowing them $1 a day, and in extreme cases $2, for each patient. This allowance was not to be paid, however, unless the jailor applied at least once in twenty days to the Board of Directors of the hospitals, for the admission of the patient to the hospital, and the application is refused for lack of room. Owing to the crowded condition of the hospital, an appropriation of $46,000 was made for buildings for a second hospital.

County Clerks were ordered to keep separate books for the registry of physicians and accoucheurs, and for marriages, births, and deaths, and to report annually concerning the same. A failure to obey made the clerk liable to a fine of $100.

It was declared unlawful to sell or give to any minor under sixteen any cigarettes or opium in any form. A violation of the law was made a misdemeanor and punishable by a fine of $100 and imprisonment for six months. An exception was made for prescriptions containing opium when given by a regular practising physician.

The manufacture or sale of oleomargarine was forbidden, unless the article was colored pink.

Wisconsin.—A drastic law was passed in this State regulating the sale of oleomargarine. Every article or mixture of the kind must be plainly marked in capital letters, and every package sold must have a label attached stating what it is.

No person is allowed to sell oleomargarine or butterine who does not keep posted in a conspicuous place a card saying "Oleomargarine sold here." Every boarding-house, restaurant, lunch counter, or hotel which uses oleomargarine must have a card plainly stating the fact.

All charitable and penal institutions were forbidden to use the imitation butter under a penalty imposed upon the superintendent of from $25 to $50 for the first offence, and $50 to $100 for subsequent offences, together with imprisonment not exceeding ninety days, at the discretion of the judge.

The statute forbidding the killing of song birds or the destruction of their eggs and nests, was amended by striking out the "sparrow," though no bounty was given for the bodies as in Illinois.

Power was given to county and municipal judges to send deaf, mute, or blind children to some public or private institution for education, if the parents or guardians neglected to properly care for them.

Children under fourteen were forbidden to be employed in factories, places of amusement, except in the service of their parents and out of school hours.

The sale or gift of cigarettes or tobacco to any minor was forbidden when such sale or gift had been prohibited by the parent or guardian.

The offence was made a misdemeanor and punishable by a fine of $25.

Wyoming.—Considerable of the legislation of this State was significant of its recent admission in the Union.

A Board of Trustees was provided for the State Blind, Deaf and Dumb Institute, and it was directed to be opened when at least twelve pupils were ready to enter. If the number of pupils at any time was less than eight, the Institute should be closed. An appropriation of $750 was made for expenses.

A comprehensive statute for the protection of children was passed. Their ill-treatment, over-work, and cruel punishment was forbidden, also the employment of minors under eighteen as acrobats, gymnasts, rope-walkers, or in any indecent and illegal occupation.

Children shall not be given or hired out to sing or beg, and no one having the care or custody of children shall allow them to dance, or act in any concert saloon or place where liquor is sold.

No child under fourteen shall be allowed to work in any colliery, iron mine, or underground workings.

Any duly organized or incorporated humane society may have its officers commissioned as police, but without compensation.

A State Board of Charities and Reformatories was organized, and authority given to it to examine and supervise the management of all charitable, reformatory, and penal institutions. An inspection must be made at least once a year.

The appointment of all officers of penal and reformatory institutions was vested in the Board.

County Sheriffs were directed to report twice a year the condition of the jails, and the number, habits, occupation, cost of medical treatment, etc., of the convicts.

No convict was to be employed so as to compete with

honest labor. An annual report, with any recommendations thought proper, was directed to be made to the Governor.

The determination of the question of insanity and the capacity to manage property was confided to a jury of six persons. If found insane a guardian was to be appointed. If subsequently it was claimed that a person had become sane, this question was to be submitted to a jury.

The same proceedings were authorized in cases of habitual drunkenness, where the person was incapable of managing property.

The salary of the State Veterinarian was reduced from $2,500 to $1,800; and the age of consent in cases of rape was raised from fourteen to eighteen, and the punishment placed at a period from one year to life.

The question of establishing a Home for Friendless Women and Children was directed to be submitted to the people at the next general election.

(Concluded.)

Progress of Medical Science.

Adenoid Vegetations.—Adenoid vegetations in children are removed by the following simple method, given by Dr. Dessar (*Archives of Pediatrics*, May, 1892): The experience of the author has taught him that adenoids in children are best removed in a series of operations without an anæsthetic, rather than in a single sitting under anæsthesia. He seldom has to resort to any instrument outside of three sizes of Lowenberg's forceps. The child is placed either in a chair or the mother's lap, and the arms held firmly, the forceps are then quickly introduced into the vault of the pharynx, pushed up as high as possible, the blades widely separated, then closed, and the sheaf of the instrument slowly forced downward. If too much resistance is encountered too much tissue has been grasped. Much harm may be caused by improper or poorly constructed instruments. After one or two sittings children usually become more courageous and the mouth-gag is not necessary. Sittings are continued until digital examination reveals a smooth surface on the vault of the pharynx. Adenoid tissue on the lateral walls and in Rosenmueller's fossæ are to be scraped off with a lateral cutting curette. The author has devised two small instruments, made by Reynders, one edge being blunt, and made to cut one from right to left, and the other from left to right. The advantages gained in operating on children in the foregoing manner are: 1. The absence of disagreeable symptoms following the use of an anæsthetic. 2. The absence of profuse hemorrhage. 3. The absence of pain after the operation, and of bronchitis brought on by blood entering the bronchial tubes, as so often happens after anæsthesia. 4. Short time consumed in operating. 5. The consent of parents objecting to an anæsthetic.

Transplantation of Large Skin-flaps.—Wolfe's method of skin-grafting is quite different from the epidermic methods of Reverdin and Thiersch. Dr. Ceci, of Genoa, reported seven cases on which he had used this method, at the International Congress in Berlin. He now reports three more cases, with illustrations, in *The British Medical Journal*, April 16, 1892. Flaps taken from distant parts undergo contraction in the course of years, but this is also true of the Tagliacozzi, and the migration (*Wanderlappen*) method of Hacker and Obalmiski. The Wolfe method is thought admirably adapted to plastic operations on the forehead, cheeks, surface of cranium and nose, where the bones are intact. The following modifications are suggested: 1. In gradually reducing the number of sutures I have at last given them up altogether, finding that the flap adheres like sticking-plaster. 2. Instead of transplanting the skin at once after preparing the surface, I find it better to allow two or three days to intervene. This is especially imperative when arteries have been tied, because these bits of sloughing tissue may have a septic effect upon the transplanted flap. 3. To obviate the objection of cutting an irregular flap to the required shape and measure, and thus leaving a granulating sore on the arm, I remove it in a straight line, whereby I obtain a lineal cicatrix.

Laryngitis from Iodide of Mercury.—Dr. Kanasugi (*Berlin. klin. Wochens.*, No. 36, 1891) reports an instance of sudden acute laryngitis following the use of calomel by insufflation while iodide of potash was being given by the mouth. The night following the first application of the calomel, sudden hoarseness and suffocation occurred and there was great difficulty in phonation. Œdema was found involving the epiglottis and arytenoids, while parts or the mucous membrane within the larynx looked as though nitrate of silver had been applied. The drugs were discontinued and the œdema disappeared.

Pental.—Dr. Holländer (*Therap Monat.*, January, 1892), has recently succeeded in producing profound narcosis with pental inhalations. The effect begins within forty to forty-five seconds, and consciousness is lost in from one to three minutes. Corneal reflex persists for a long time. On waking the patient feels well. The new anæsthetic is recommended for short operations.

Sulphonal, its Dangers and Disadvantages.—Among the disadvantages in the use of sulphonal Dr. Johnstone finds the slowness of its action, and the tendency of the action to be prolonged into the succeeding day. It also is found to be followed by drowsiness, confusion, giddiness, fatigue, and serious cerebral and motor symptoms when repeated doses are given.

Dr. Fürst (*International klin. Rundsch.*, Nos. 48, 49, 1891) has noted such numerous and disagreeable symptoms as twitching of the muscles, nausea, vomiting, vertigo, fainting attacks, tinnitus, chilly sensations, paralytic weakness, ataxia, diminished pupillary action, diarrhœa (rarely), obstipation, ischuria or complete anuria, lowered temperature, cardiac weakness, impairment of respiration, cutaneous eruptions, hallucinations, and amaurosis. In spite of all this it is well known that the moderate use of sulphonal is entirely harmless. It is only when kidney disease is present or threatens that the drug should be entirely withheld.

Glandular Asthma.—Dr. Joal (*Archiv. Gén. de Méd.*, April, 1891) shows that in infants asthma is at times symptomatic of tracheo-bronchial adenopathy. The bronchial glands are often the site of congestive and inflammatory conditions following bronchitis, measles, pertussis, etc. These fluxions irritate the terminal filaments of the pneumogastric, the irritation is transmitted to the bulb and determines a spasm of the inspiratory muscles and dilatation of the pulmonary vaso-motors. This asthma is thus of reflex order, and is produced by a mechanism analogous to that which presides over the development of nasal, tonsillar, and gastric asthmas. This affection is observed especially after measles, whooping-cough, and infectious infantile diseases in those predisposed to bulbar over-activity, and especially in young boys whose parents are neuro-arthritic. The determining causes of the attacks are those which provoke fluxion toward the intra-thoracic glands. Emotions, weeping, effort, variation of temperature, chilling, etc., interfering with respiration, may cause similar congestion of the glands. Glandular asthma is to be suspected if the paroxysms return, especially by day, after efforts and movements; if they appear and disappear coincidently with swelling of the glands; if they coincide or alternate with the pertussis, vomitings, palpitation, aphonia, persistent hoarseness. In treatment, cutaneous revulsion has a great importance. It should be prolonged, but not painful. Other treatment, as for infantile asthma in general, special treatment being at the same time directed against the adenopathy.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 43, 45 & 47 East Tenth Street.

New York, June 4, 1892.

THE AMERICAN MEDICAL PROFESSION AND THE CABINET.

IF the great American medical profession goes and makes a fool of itself, the fact, however painful, ought to be made known for purposes of self-mortification, self-instruction, and future guidance. We are not prepared to admit that so inopportune and unexpected a thing has happened, but there are facts which it must be confessed suggest it

Last fall Senator Sherman, of Ohio, introduced a bill to establish a Medical Secretary of Public Health. This bill was the creation of a committee of thirty, appointed by the American Medical Association to promote the object contained therein. What this Secretary would or ought to do is modestly stated in the following paragraph, which forms part of a highly desultory preamble.

"A Secretary of Public Health would represent the medical consciousness of the nation, and become one to whom we could look for the exploitation of measures that will direct continuous scientific and collective investigation in regard to endemic, contagious, and other diseases; the enlightenment of the people in sanitary ways of living; the dissemination of information respecting the most favorable places of residence for those afflicted with such chronic diseases as asthma, rheumatism, neuralgia, and consumption; the examination of food and drinks; medicinal springs; the collection and tabulation of vital statistics at large and in various localities, such as the congested areas of our great cities and among various races. He would be able to co-operate with State Boards of Health, the Signal Service, the medical departments of the army, navy, and marine service, unify and utilize their work, and thus make the Department of Public Health the repository of the most important facts that concern the comfort of the people, and his duties will grow broader and stronger in adaptability to public needs. Moreover, the creation of this department will be a declaration by Congress that the promotion of the health of the people is a supreme law, and that in the future progress of civilization medicine shall have its true rank with the other offices of the State."

So far this is good enough, and if the energetic committee had confined itself to the eloquent presentment above, it would have caused no great comment.

But the preamblers were not content. Being appointed to memorialize it was bound to give Congress its money's-worth. It proceeds to dilate therefore upon the greatness of the American Medical Association, "constituted, as it is, of men of distinction in their profession in every part of the Union." It complains that in the United States the medical profession has been left, for the most part, to take care of itself, "without subvention of the State." But despite this, it adds that "there is no other profession that excels ours in positive efficiency to sustain public order, comfort, and virtue. We possess vast capacity for the direction of society and promotion of human happiness."

The following interesting and no doubt truthful disquisition on the general theory of medicine is an illustration of an earnest but misapplied enthusiasm:

"The organism which is called medicine, like every other product of man's constructive genius, is striving to attain perfection, and to accomplish this it must be sustained in all its scientific undertakings by the co-operation of national and State legislation and the hearty co-operation of the people for whose health and happiness all its efforts are put forth to prevent disease. It is certainly a remarkable spectacle to observe its constant effort to save the people from disease, when success will limit to the smallest dimension the office of physician. But this grows out of the nature of their studies, the tendency of which gives the highest motive for unselfish service to suffering humanity. The physician is bound to render this service to rich and poor alike. The amount of gratuitous service, especially in great cities, constitutes one-third of their practice. The most distinguished and experienced of the profession form the staffs of all of our hospitals, without any remuneration."

It will, we think, appear to all of our readers that however rich in truth these paragraphs are, they would not appeal to the average Congressman as reasons for creating a Medical Secretary of Health.

We quite believe in the utility of such an office, and in the fact that eventually it will be created. But it cannot be gotten by means of pathetic recitals of medical wrongs or of medical philanthropy. If we have a Medical Secretary it must be because such a person will be distinctly a benefit to the people and the State. A memorial based on this ground, containing facts logically arranged and cogently presented, would win votes, and each year it would secure more. Let the committee of thirty start again, tear up its rhetoric, leave out the dispensary question, and appeal to Congress on a more solid basis.

CORYZA AND THE AXIS OF ASTIGMATISM.

OUR esteemed contemporaries the *Medical News* and the *Post-Graduate* are adding much to the gayety of nations and the joy of medical ratiocination. A contributor to the latter journal intimates that Philadelphia ophthalmology is lagging behind, and does not understand or properly apportion the use of atropine and ophthalmometers. To which the Philadelphia editor utters paragraphs of scorn, and affirms that life is too short to be spent in correcting the errors and vagaries of New York's *fin de siècle* oculists.

Comes now the *Post Graduate* and girds itself against its disdainful opponent. "A writer in the *Medical News*," it says, "reports a case of severe common cold

due to reflexes from the eye. A man of forty-six years of age, a successful business man, came to the author on account of asthenopia. After paralyzing his accommodation, it was found that he had three quarters of a diopter of myopia in one eye, and one and a half in the other."

This statement brings the *Post-Graduate* critic into a condition of surprise, stasis, and awe. A man of forty-eight years, we re assured, does not need his accommodation paralyzed—nature has already done that for him—in order that his refraction may be determined. "This plan has not even the merit of being an ancient practice. We have never heard that oculists in general paralyzed the accommodation of patients who are more than forty two. With glasses alone, the refraction of such patients can be accurately determined in a short time, and with the ophthalmometer in five minutes."

Nevertheless the glasses cured the coryza of eighteen years' duration, including a pharyngeal and laryngeal congestion and a change of voice. If the axis of the astigmatism became improperly rotated, the coryza reappeared.

It looks as though astigmatism was going to become more epidemic in Philadelphia than heteraphoria ever was in New York.

We shall watch the progress of the ophthalmological civilities between the two towns with much interest. Meanwhile the reckless general practitioner will probably go on treating coryza in the old and ignorant way with aconite, Dover's powders, quinine, and expectation.

A PARTIAL SOLUTION OF THE DISPENSARY PROBLEM.

If Theophraste Renaudot had known the amount of talk that would be occasioned by dispensary abuses he would have hesitated at least before establishing his first institution for the free treatment of the ambulant sick. However, there is some satisfaction in knowing that all the talk has not been vain. We have tried to do our part, and it is gratifying to know that others interested in this important question have succeeded in a measure in practically correcting some of the abuses to which we have so often referred in these columns.

In this issue will be found the announcement of a competitive examination to fill a vacancy in the medical staff of the Good Samaritan Dispensary (formerly Eastern) at a salary of $600 per annum. This has led us to make some inquiries concerning the institution's management and resources, and we have learned that over $10,000 are paid out each year in salaries to the doctors who do the work, and that this amount, and a small surplus besides which goes toward paying for the drugs, comes from the patients treated, so that it is practically a co-operative institution. Each patient, if able, pays a fee of ten cents, and, according to the report, almost one hundred thousand prescriptions were paid for last year, and nearly seven thousand were dispensed free. Surgical operations, dentistry, and vaccinations furnish an additional source of income. The only strictly charitable feature of the institution thus seems to be the furnishing of a building in which the work can be carried on, and the dispensing of medicines at about one-third their cost.

There is unquestionably a large number of people in this city who can readily pay so small a fee as ten cents, while it would be almost impossible for them to pay a physician a dollar fee in his office, especially if it were necessary, as it usually is, to make frequent visits. Now, if this institution or any other can and will treat this class to the exclusion of the others who are able to pay for treatment outside, the problem is solved.

The report shows that nearly ninety-one thousand patients were treated last year. It does not show how many were refused treatment, but we are informed that the rules permit any physician to refuse to treat any patient whom he deems unworthy, and that a certain proportion are thus excluded. Investigation of the condition of suspected frauds has been found unsatisfactory and expensive, but the management expresses itself as ready and willing to institute as thorough investigation in this direction as possible if a fund can be established for this purpose. This would seem to be a much needed reform, and in the absence of a detective bureau attached to each dispensary we would offer the suggestion of refusing treatment to all suspected applicants, and let the burden of proof rest with them. On application to the Association for Improving the Condition of the Poor, the Charity Organization Society, or similar body, a certificate could be given the applicant showing that his condition had been investigated, and that he was entitled to free or low-price co-operative treatment.

Until all the dispensaries in the city join in some such combined effort abuses will continue, and it will surely be to the disadvantage of those institutions which refuse to make any attempt to correct them. The impression is gaining ground that there has been about talk enough, and that the time is fast approaching when action will be required.

The Medical Record is glad to lend its support to any institution making a true effort to do the proper thing by the physician while not pauperizing the public, and it will continue to oppose all those whose methods injure physician and public alike.

THE CORRESPONDENCE OF THE INSANE.

Among other wonderful things done by the late Legislature of this State was the enactment of a law prohibiting "the opening or reading of certain letters written or received by the inmates of insane hospitals and asylums by those in charge thereof, and providing for the delivery of the same."

This bill was lobbied through by a lady who had at one time been unfortunate enough to suffer from an attack of insanity, and who represents a curious organization called the Anti kidnapping Society. The bill provided that every lunatic should have the opportunity once in three months of choosing a correspondent with whom he or she could communicate weekly. The letters sent and received must not be opened or examined.

The bill was unnecessary, harmful, and absurd; but it nevertheless passed both houses. A very forcible brief was drawn up by Dr. A. E. Macdonald and presented to the Governor. Protests from various other sources were received and the bill was fortunately vetoed. Dr. Macdonald says in his "brief:"

"There are in the city asylums at present patients who claim to be the husbands, or accepted lovers, of many ladies of prominence, several of them married, whose names can be given to his Excellency, privately, if he desires it.

"The patients further claim that they are separated from these ladies by their husbands or other relatives.

"They will undoubtedly select these ladies as their 'chosen correspondent,' and overwhelm them with offensive protestations; or they will select the husbands or relatives, and threaten them with violence of all kinds.

"Should these ladies and gentlemen be exposed to such attacks, and deprived by law of the right to protect themselves?"

The law already existing provides that letters directed to public officials shall not be opened; and furthermore all correspondence not approved or detained by the superintendent must be forwarded to the State Commission, by whom an examination is made. If the letters are proper they are then forwarded. Present regulations thus sufficiently respect the rights of the insane and protect the sane from insult and annoyance. We trust that no further attempts will be made to disturb a system which proves to be safe and just.

News of the Week.

A Novel Cure for Diarrhœa.—Dr. Samuel P. Hand, of Cootopa, Ala., reports the case of a negro woman three months pregnant, suffering from typhoid fever, to whom was given internally, by mistake of an attendant, two teaspoonfuls of tincture of iodine in twenty-four hours, without toxic effect. Paregoric in that quantity had been prescribed for a diarrhœa, but the tincture of iodine apparently cured the diarrhœa; at least, it did not kill the patient nor the prospective child.

The Deeds of Ohio Statesmen.—There are spectacles for gods and men, and also at times for their gibbering simian ancestors. Something of the monkey trick spirit seems to hang over the Ohio State Legislature. This eminent body of statesmen, as we learn from the *Journal of the American Medical Association*, has, "with considerable merriment, rejected a bill to regulate the practice of medicine in the State, principally because it would interfere with itinerant doctors, and diminish the advertising receipts of some papers." It did not adjourn, however, without affecting any medical legislation. It appropriated $5,000 to test the efficacy of the Keeley cure, and made itself a sort of committee of the whole to investigate. Each member is to have the privilege of sending one patient!

The Prince and the Doctor.—The well-known English physician, Dr. Sinclair Coghill, recently sued Prince Clovis Bonaparte for compensation for services in having attended Madame Rosalie Bonaparte when she was sick. In answer to Dr. Coghill's suit, Prince Clovis asserted that the services performed by the doctor were not of a character for which a husband ought to pay, and that the relations between Dr. Coghill and Madame Bonaparte had been not medical, but immoral. Dr. Coghill's answer to this was that Prince Bonaparte was only a blackmailer, and was trying not only to evade his honest debt, but also to extort money by making false charges, and that it was with the view of meeting this issue squarely that he, Dr. Coghill, had brought this suit. The jury believed the doctor, and disbelieved the Prince and Madame Bonaparte. They gave a verdict to Dr. Coghill for the full amount of his claim.

Antifebrin and the Tuberose Smell.—We hear of an observant gentleman of David City who takes a dose of antifebrin and then goes out into the open air, whereupon he smells a beautiful odor somewhat resembling the tuberose. This curious psychological experience has been repeated so often that the relation of the tuberose to the hydrocarbon product is established. The question only remains, is this a universal law, or only limited to David City? There are times on summer nights when the citizens of New York would gladly antifebrinize themselves if it would shut out the evidences of industrial activity on a neighboring island.

A New Medical College for Chicago.—The present medical colleges of Chicago are not sufficient for its greatness, and a new institution, to be conducted on new lines and in a thoroughly fresh and, we take it, "brainy" way, is proposed. The name of the new institution is the "Clinical College of Medicine and Specialty Hospital," and it already has a lot 131 × 182. Instruction is to be given by demonstration and recitation. No didactic lectures will be given. We should judge that the Clinical College has got the right ideas of teaching, but it will find that the new methods are very expensive.

Improvements in the Army Medical Service.—The army is to have one hundred new ambulances, and there are to be additions and improvements in the medical equipment of the corps which will place that important branch of the service upon a more efficient footing than the medical corps of foreign armies. The hundred ambulances to be built will replace the old ones as far as possible. The new ambulance is three hundred pounds lighter than the present vehicle. It is a four-wheeled affair, strong enough in construction to withstand the wear and tear of hard road travel, and equipped with springs to prevent undue jolting of the occupant. The new medical and surgical boxes, quite ingenious repositories of every conceivable description of physician's material, find places under the seat of the driver. Two oblong boxes, one on each side of the centre of the wagon, slide in and out, affording easy means of carrying water, a gallon of which is contained in each receptacle or drawer. The floor of the wagon has grooves, into which the feet of the litters are placed for sliding them into steady positions in the ambulance, which accommodates two litters, side by side. A step is affixed to the tail of the wagon. Leather-covered seats, capable of being folded out of the way, extend along each side of the ambulance, which is protected from weather by a roof and removable curtains of white canvas, supported by framework. The litters can be carried folded in a compact bundle, when not in use, in a sling on the outside of the wagon. Another sling accommodates an extra pole.

The Inebriety Cure in London.—Dr. Keeley has taken his "cure" to London, and after consultation with a certain Texas colonel, of sporting and political fame, has

decided to submit his treatment to the critical examination of Mr. Henry Labouchere, editor of a weekly newspaper! This is a pleasant and modest way of finding the truth. We submit to expert Labouchere the following item from the *Pittsburg Dispatch*: "Eleven graduates of the Keeley Institute are now inmates of the Illinois Eastern Hospital for the Insane, at Kankakee; ten of these had never been previously confined in a hospital."

The Death of Professor A. W. von Hofmann, Professor of Chemistry in Berlin, is announced. Professor Hofmann was the discoverer of the aniline dyes, and indirectly modern bacteriology is due to Hofmann's work.

The Sixtieth Annual Meeting of the British Medical Association will be held at Nottingham on Tuesday, Wednesday, Thursday, and Friday, July 26, 27, 28, and 29, 1892.

A Medical Memorial.—Mr. Lawson Tait lately unveiled a fountain and clock tower, at Willenhall, to the memory of Dr. Joseph Tonks, a young doctor of thirty-five. The day was observed as a general holiday. At the dinner in the evening, Mr. Tait is reported to have said that honors for the medical profession were not very common. They got a few honorary degrees—though those were not worth much—which often they did not deserve; then there were a few titular distinctions, such as knighthoods and baronetcies. He had had the pleasure of refusing the one, and he did not expect he should ever have the chance of refusing the other. If he had his choice of honors he should be inclined to say: "Set up to me in the market-place a clock and a fountain, which would keep the people punctual and would slake the thirst alike of tired men and beasts." He had rather have that dead than a baronetcy alive.

The Fuchsin Bodies and Cancer.—Dr. Sims Woodhead, in his Morton Lecture on the Etiology of Cancer, corroborates Dr. Russell's observations as to the presence and probable importance of the fuchsin bodies in cancer.

German Congress of Internal Medicine.—At the sitting of the Congress of Internal Medicine, on April 22d, Professor Rosenstein, of Leyden, spoke on chronic hepatitis. In Germany, he said, the opinion still prevailed that the two morbid conditions of the liver are only different stages of the same disease, and that the stage of enlargement precedes the other. Professor Stadelmann, of Dorpat, declared inadequate the reasons adduced for the opinion that hypertrophy and atrophy of the liver were different diseases. Among the causes which specially favor the latter condition he mentioned the copious consumption of alcohol, chronic lead-poisoning, syphilis, tuberculosis, and malaria, but maintained that there were many cases of which it was impossible to trace the cause. Nor were the causes of jaundice, one of the most characteristic symptoms in the hypertrophic stage, sufficiently cleared up. Professor von Frey, of Leipsic, reported the important fact, ascertained by experiments on animals, that the jaundice which follows the closing of the biliary passages leading from the liver did not supervene if the ductus thoracicus was ligatured. Dr. Israel, of Berlin, reported the results of his investigations on the secondary alterations in the organs of circulation when the action of the kidneys was insufficient. Dr. Krönig, of Berlin, gave an account of an injecting apparatus which he had constructed. Dr. Schmidt, of Breslau, showed microscopic preparations in which the characteristic formations of pulmonary asthma in the smaller bronchi were beautifully visible. Dr. Martins, of Rostock, reported the results of a series of very careful chemical analyses, undertaken with a view to ascertaining the quantity and the manner of the appearance of the hydrochloric acid in the stomach in digestion. He stated that it is secreted in the stomach, uncombined, immediately on the entry of the food. Professor A. Fränkel, of Berlin, spoke on cancer of the costal pleura. Dr. Hoppe-Seyler, of Kiel, reported his investigations of the fermenting processes in the stomach, and of the gases developed by them under various conditions. Professor Unverricht, of Dorpat, discussed the manner of the occurrence of Cheyne-Stokes breathing under the influence of various poisons and morbid processes, and explained it as a symptom of cerebral collapse. The following three speakers treated of tuberculosis in connection with the comparatively small number of cases in proportion to the enormous opportunities of infection, and arrived at the conclusion that far more people were infected than was known. In the greater number of cases the tubercle bacilli were rendered, either permanently or temporarily, harmless by the resistance of the tissues of the body. In the latter case they remained in the body as latent foci, which become active when the resisting power of the body diminished. Dr. Spengler, of Davos, reported the results of the treatment of pulmonary phthisis with tuberculin and tuberculocidin (tuberculin purified by Klebs) combined. Dr. Cornet, of Berlin, drew attention to mixed infections in pulmonary tuberculosis, and maintained that the dangerous feverish conditions which set in with rapid decay of the lung-tissue, in the course of otherwise slow pulmonary tuberculosis, were not due to the tubercle bacillus alone, but to other bacteria also—streptococci, staphylococci, etc. The first speaker on the 23d was Dr. Mannaberg. His discourse was on the subject of malaria, and he maintained that the semilunar micro-organisms appearing in malignant cases were neither products of degeneration nor a definite species of disease germs, but cyst-formations produced by the fusion of two or four of the young micro-organisms in the red blood-disks, and generating new ones by sporulation. The Congress was closed by the Chairman, Professor Kürschmann. Next year's Congress will meet at Wiesbaden.—*The Lancet.*

In a Discussion on the Dispensary Abuse before the Lenox Medical Society, Dr. W. K. Simpson stated that while the dispensaries were founded on the idea of charity, the element of charity in them has almost disappeared. It is difficult to ascertain the patients' status, as they make false statements. Two-thirds of the people who go to the Vanderbilt Clinic give fictitious names and addresses. The physicians who attend at the dispensaries should receive a fair compensation for their work. People who apply at the dispensary one day should not be treated (except in emergency cases) until the day after, thus giving time for investigation.

A New Hospital, called Grace Church Hospital, is to be built in this city soon.

Society Reports.

ASSOCIATION OF AMERICAN PHYSICIANS.

Seventh Annual Meeting, held at Washington, May 24, 25, and 26, 1892.

DR. HENRY M. LYMAN, OF CHICAGO, PRESIDENT.

FIRST DAY, TUESDAY, MAY 24TH.

President's Address.—DR. LYMAN, in his brief address, referred in eulogistic terms to two recently deceased members, Dr. Donaldson and Dr. Bowditch. No epoch-making discovery had been made in medical science during the year. Suggestive studies, however, had been made in electricity, tending to show it depended upon motion in an ether; in microscopic studies bearing upon fecundation and heredity; opposing views, explaining the same phenomena by chemical and physiological forces. Among valuable works which had appeared during the year had been Eichorst's volume on medicine, Osler's on the practice of medicine, and others by French authors. The world, he said, could no more dispense with the service of the French than with those of the Germans.

A Bacteriological Study of Drinking-Water.—DR. V. C. VAUGHAN, of Ann Arbor, Mich., in his opening remarks in a paper on this subject, stated that he had no new discoveries to announce, but simply wished to make a communication on the results of his labors in the study of drinking-water the past three years. They were both chemical and bacteriological. During this time he had made a study of one hundred and forty-eight samples of water sent him from different places. In most instances they were suspected of being the cause of disease, usually typhoid fever. It had been found that the number of germs in a drop of water varied greatly, and bore no constant relation to the amount of organic matter in the water as determined by chemical analysis. The question of the fitness of the supply as a drinking-water it was found could not be answered by the number of germs. During his investigation it was recorded in what manner the germ grew on gelatine plates, in gelatine tubes, on agar, on potato, etc., also the form and size of the germ, its reactions with staining agents, etc., likewise its effects upon guinea-pigs, mice, etc. He had given especial attention to those characteristics by which it had been proposed to distinguish the typhoid germ from other bacteria found in water.

They had found that many germs present in drinking-water did not grow at a temperature of the human body, and therefore they were incapable of inducing disease, including typhoid fever. The water, however, might not be desirable for drinking purposes. Of the germs which grew at 38° F., or a higher temperature, some were fatal to animals when injected subcutaneously, others were not. The former he distinguished as toxicogenic; the latter as non-toxicogenic. He made a distinction between non-toxicogenic and pathogenic germs. In the case of non-toxicogenic germs, there was no proof that they could multiply in the animal body. Waters containing such germs had not been positively condemned, although he had advised in some cases that their use be discontinued. Some of the toxicogenic germs found in drinking-water produced the same symptoms, and the same post-mortem appearances in the animals experimented upon as were observed after the use of Eberth's germ. They not only lived, but multiplied in the animal body. He condemned all waters containing these germs. As to the statement that only Eberth's, or the so-called typhoid-fever germ, would form an invisible growth on potato, this had been shown not to be true, for more than one of the germs which he had found in drinking-water also produced invisible growth on the potato. The tests which had been advanced by Parietti, also that advanced by Uffellmann, for the Eberth germ were not reliable, since they applied equally to several of those which he had described. Thirty-one of the germs found in the one hundred and forty specimens of water had been studied sufficiently to admit of their identification. Twenty-four of these failed to grow at a temperature of 38° F., seven grew at this temperature, and of these seven, four killed animals when injected subcutaneously; three did not.

DR. STERNBERG said that there could be no doubt of there being species among these germs, as there were in the vegetable kingdom, with shadings into one another so gradual that it was sometimes difficult to place them. The typhoid bacillus, he said, did not always have an invisible growth on the potato, and other germs might have on the same vegetable an invisible growth. It would thus be seen that there was great difficulty in differentiating these lower organisms.

DR. WELCH, of Baltimore, doubted the propriety of using the term "toxicogenic" as distinguished from "pathogenic." He knew of no means of recognizing the Eberth germ positively, without it were obtained from the spleen of one dying of typhoid fever. He believed the test with milk thus far was the most useful one. He referred to the great liability of mistaking the bacterium coli communis for the typhoid and other germs.

DR. VAUGHAN said there was one part of this work which he had not been able to do, which was to obtain the spleens of persons dying from the disease produced by drinking the waters sent in for study, and studying them in relation to the germs found in the water. He had been able to exclude the bacillus coli communis in these investigations. He said there was no doubt but that in great cities typhoid fever commonly arose from drinking-water which had been polluted from typhoid stools, but his own investigations had been mostly in towns where the water was obtained from different sources. He believed that different varieties of the same germ, or different germs, might cause typhoid fever, and he did not believe that these necessarily had their origin in a previous case of typhoid fever. Again, there was evidence to show that in man, as well as in animals, a tolerance to toxic germs might be developed, so that a person might carry the disease (typhoid fever) to different communities while not suffering from its symptoms himself.

The Cold-Water Treatment of Typhoid Fever.—DR. G. WILKINS, of Montreal, in the first part of a paper bearing this title, referred to the work of Brandt, Liebermeister, and others. Having himself obtained better results from this method than from any other in a like number of cases, he was induced to give his experience. The total number of cases treated by him with the cold bath was thirty-nine. He had not, however, adopted it exclusively, for during the same period he treated nine cases by what may be termed the expectant plan. The greatest number of baths given any one patient had been thirty five. Nearly all patients objected to it; yet afterward they felt refreshed, and usually fell asleep. The temperature continued to fall for about half an hour. It usually fell altogether two or three degrees. The pulse was reduced from a few beats to eighteen or more. Two patients had died, one having had serious bronchial complications on admission. The duration of the temperature averaged thirty days; treatment was begun usually on the tenth day. The beneficial results were due in no small degree to reduction of the temperature, but also in large degree to the impression upon the nervous system. By action upon the vaso-motor nerves it caused the blood-vessels to contract, and forced the blood along and relieved internal congestion. Where the heart muscle had become degenerated, it was possible it might be overwhelmed by the amount of blood suddenly driven to it. Further contra-indications were hemorrhage and peritonitis.

Cold Baths at Johns Hopkins.—DR. WILLIAM OSLER, of Baltimore, said the deaths in 32 cases treated symptomatically at Johns Hopkins, prior to July, 1890, had been 7; in 107 cases treated since that date by the

Brandt method, the deaths had been 8. The results from the cold-water treatment had been practically those obtained in other large general hospitals, markedly better than by other methods. In only 89 of the 107 cases was the bath indicated or resorted to, as the temperature did not rise above 102.5° F.

Dr. F. P. Kinnicutt, of New York, said he had not the statistics of typhoid fever in St. Luke's Hospital with him, but he thought they confirmed the experience already given, that the cold water treatment was attended by a much lower death-rate than any other. Indeed he thought it was the only method which could be entitled a treatment of typhoid fever. The largest number of baths, 175, were given a patient, son of a physician, who was the most ill of any whom he had ever known to recover.

Credit to Hiram Corson.—Dr. William Pepper, of Philadelphia, wished to give credit to Dr. Hiram Corson, of Montgomery County, Pa., a practising physician, ninety years of age, for having persistently and systematically used cold-water treatment in infectious diseases, especially typhoid and scarlet fever, the past sixty years. He said that Dr. Wilson, of Philadelphia, had done more than any other American to introduce the method here generally among the profession.

Dr. Pepper went on to confirm the very excellent results related by others as attending the cold-bath method in typhoid fever, and said that where it could not be applied much benefit was found in the cold pack. The labor of applying the bath was less, however, than that of the pack. He had introduced a collapsible tub, which could be used in private as well as in hospital practice, and hoped there would soon be statistics of collective investigation showing the value of the Brandt system in private practice. He also impressed the value of thorough friction following the bath.

Dr. J. E. Atkinson, of Baltimore, spoke approvingly of the method, but said it should not be forgotten that there might be serious and fatal cases of typhoid fever in which the temperature never rose above 102° F., or to that at which the bath was said to be indicated.

Dr. W. G. Thompson, of New York, said that during the past two years he had treated forty-eight cases of typhoid fever by the Brandt method at the New York Hospital, with a mortality of about seven per cent., whereas the previous mortality by other methods had been about nineteen per cent. He attributed the benefit less to reduction of the temperature than to the nervous influence of the shock from the water, and afterward the friction. He thought the danger of hemorrhage from driving the blood to the internal organs had been much exaggerated.

Dr. Tyson, of Philadelphia, had not thought that friction was important except for its influence upon the patient's mind.

Dr. Stockton thought the baths might prove beneficial in cases in which the temperature never rose to 102.5° F., by favorably influencing the nervous system.

Report of 2,012 Cases of Alcoholism, of which 87 were Maniacal.—Dr. T. S. Latimer, of Baltimore, read a paper giving a brief history of 2,012 cases of alcoholism, less than one-half of which he had reported in a previous paper. Eighty-seven of the total number were maniacal. Nearly all of the patients were arrested for drunkenness or misconduct of some form due thereto. They were what were termed by jailers as "regulars." Some of them were addicted to the use of cocaine, chloroform, and other stimulants besides alcohol. It was apparent that they were a very unfortunate class of cases to treat, having been badly fed, badly clothed, badly housed, addicted to stimulants, often suffering from other diseases. Almost invariably they begged piteously for drink, which, however, was invariably refused. None remained delirious longer than five days. The average time before they were able to do what little work that was required of them was two days. By the second night they almost invariably could sleep well. Except in a very few instances the only drug given was bromide of potassium. The good result, however, was not attributed so much to the drug as simply to the withdrawal of alcohol, which was absolute and from the very commencement. No restraint was put upon the patients farther than to keep them shut in their cells.

The conclusions were: 1, That the clinical phenomena attending the excessive use of alcohol were the direct result of the stimulant, and were not due to abrupt withdrawal of it; 2, that the desire for the stimulants almost uniformly persisted; 3, that alcohol in any form or quantity was unnecessary in the treatment of such cases, and was usually harmful; 4, that absolute and immediate withdrawal of alcohol was of the first importance in treating the symptoms due to its use; 5, that forced feeding was rarely necessary; 6, that placing the patient in any kind of bands was unnecessary.

Dr. Garland had seen two cases of fatal vomiting occurring in alcoholism, and inquired whether it were common.

Dr. Latimer replied that he had seen hemorrhage in only one case. He thought that where it existed it was due to cirrhosis of the liver, with the other changes which this implied.

Dr. Osler had seen one fatal case of hemorrhage in alcoholism, and in that patient there was cirrhosis of the liver.

Practical Results of Bacteriological Researches.—Dr. George M. Sternberg, of the United States Army, in a paper with this title stated that while science did not demand practical results, yet medicine, being eminently practical in its aims, sought to make practical application of the knowledge which science revealed. Bacteriologists had discovered a number of germs which were the cause of different diseases, without being able to propose a remedy based upon such knowledge. Recently, however, experimental evidence had been obtained which furnished reason for the belief that in a number of infectious diseases, at least, the toxic bacterial products which gave rise to the morbid phenomena characterizing these diseases might be neutralized in the infected individuals by the administration of anti-toxines obtained from the blood of immune animals. He reviewed some of the recent experimental researches relating to anti-toxines in the blood of animals which had an acquired immunity against cultures of the bacillus of tetanus, the micrococcus of croupous pneumonia, the bacillus of diphtheria, of tuberculosis, and against the virus of rabies. It was a question whether the anti-toxine in the blood of these animals was the product of the living cells of the body. If so, its supply would seem to be continuous. Dr. Sternberg suggested the possibility that the anti-toxine was not reproduced, but remained in the body, which would account for continued immunity. This view, however, seemed to be controverted in the case of tetanus, in which the young obtained immunity from the milk of the immune mother. In the case of this disease, tetanus, there had now been reported as many as six cases in which a cure had apparently been due to injection of serum into the circulation of the patient from an immune animal. Reasoning from analogy, it was thought possible that a cure might be effected in a similar manner in a case of other infectious diseases, such as scarlet fever, etc.

At the author's suggestion, Dr. Griffith, of Brooklyn, who had had a great amount of experience in the vaccination of cows, had carried out certain instructive experiments. He had inoculated a calf with one vaccine point which had been put into the blood-serum of another calf which had recently been rendered immune by vaccination; also by a vaccine crust from a child, recently vaccinated, emulsified in the same blood-serum. Neither point of inoculation took. Control experiments were made. Another animal was vaccinated by the usual lymph on one side, and on the other side by lymph put into the blood-serum of an immune calf. The former produced the typical sore, the latter had no effect.

Dr. Welch, of Baltimore, expressed hope that some practical value might come from the experiments with regard to tetanus and other diseases which had been referred to by the author. He believed, however, that, so far, they were open to doubt as to the interpretation to be put upon them.

Dr. Vaughan believed we should be very slow in drawing positive conclusions from the experiments which had been made by the Italians and others. It was well known that animals could be rendered immune for a short time against certain germs without great difficulty, but it had not been shown that the immunity would continue long. He was inclined to think that the action of the anti-toxines and the toxines must be in the nature of ferment. A great deal had been said about tox-albumin, but nothing as yet had been said about it in the pure state. He did not think that it was necessary that the substance to produce these effects must be, *per se*, poisonous. Temporary immunity might be produced in different ways; for instance, a few years ago a friend of his found that one of his patients ceased to have epileptic fits following circumcision. This he practised then on a number of cases, but soon it was shown that the relief was only temporary, and the practice was discontinued. The explanation of such temporary immunity was as obscure as that brought about by many other means.

Dr. Lyman had been of the impression, some twenty years ago, that the action of toxine and anti-toxine was through fermentative process in the majority of cases.

Dr. Sternberg thought that the use of the term "ferment" in this connection threw very little more light upon the subject. He was inclined to think that the future of scientific medicine lay largely in the direction pointed out in his paper, and that, ere long, results would be obtained which would knock conservatism from under the feet of those who took this ground.

The Treatment of Experimental Tuberculosis by Koch's Tuberculin, Hunter's Modifications, and Other Products of the Tubercle Bacilli.—Dr. E. L. Trudeau, of Saranac Lake, N. Y., sent a paper with this title (read by Dr. Welch), of which the following were the conclusions:

1. Koch's tuberculin does not cure experimental tuberculosis in the guinea-pig, although its specific influence on the primary lesions is indisputable. 2. Hunter's modification C. B. contains less of the remedial principle than tuberculin, and is apparently quite as dangerous. 3. Hunter's modification B. is as efficacious as tuberculin, and is free from some of its dangers. 4. Solutions of bacterio-protein, obtained as described, from well-worked bacilli, have a doubtful, and, at best, feeble remedial influence on experimental tuberculosis. 5. They produce suppuration and serious constitutional impairment, which may result in organic disease and death. 6. The liquid culture medium in which tubercle bacilli have developed, but from which they have been removed by filtration, contains the elements which bring about reaction and cure in tubercular tissue. 7. Experimental tuberculosis in the rabbit's eye can be cured by injections of the filtered medium. 8. The permanency of such a cure has not yet been established.

Clinical Observations on the Use of Tuberculin, etc.—Dr. F. P. Kinnicutt said that at the time that Dr. Trudeau was to commence his experimental studies with tuberculin and Hunter's modifications thereof, it was understood that he (Dr. Kinnicutt) should at the same time make clinical observations in this direction. By mutual understanding, meanwhile, they had had no communication with one another upon the subject. Clinically his experience during the past eighteen months had fully confirmed the experimental studies upon tuberculin and Hunter's modifications thereof as made by Dr. Trudeau. He had found that tuberculin contained a remedial principle, but being a complex substance it was impossible to separate the harmful from the beneficial results. So far as Hunter's modification C. B. was concerned, he had ventured to use it in only one case, for the reason that it had proved dangerous.

Hunter's modification B. had proven as efficacious as tuberculin, while it was free from some of its dangers. He had treated seven cases with this modification, with the result that in two there was no change in physical signs, although improvement in the general condition took place; in one there was most marked improvement in the physical signs; in others improvement, though somewhat less marked; in the seventh case, so far as it was possible to say that a patient with tuberculosis could be cured, the cure was absolute.

Dr. Welch remarked that the studies of Dr. Trudeau had been carried out in a faithful manner, with the full knowledge of the possible sources of error. They merited the serious consideration of the profession.

The Late Systolic Murmur.—Dr. J. P. C. Griffith, of Philadelphia, read a paper on this subject, reporting three cases of late systolic murmur, in two of which the murmur was audible at the latter portion of the period between the apex beat and the second sound of the heart. The third case had a murmur in the middle portion of this period. The cases appeared to indicate that there was no appreciable pause between the termination of the systolic and the occurrence of the second sound. He held that the so-called "short silence" was not a period of cardiac inactivity. The title "post systolic murmur," which had been applied to such cases, was a misnomer, since the cases occurred during systole and not after.

Second Day, Wednesday, May 25th.

Etiology and Pathology of Dysentery.—Dr. W. P. Councilman, of Baltimore, read a paper on this subject. It was based on the study of thirty-four autopsies at Johns Hopkins Hospital. As a result of his studies, he had divided dysentery into three forms: 1, Diphtheritic; 2, catarrhal; 3, amœbic. The latter was distinguished from the others, not only anatomically, but also etiologically. He devoted considerable space to a consideration of the anatomical changes found in this form, which will be given later.

The diphtheritic form was characterized by necrosis of the epithelium and by fibrinous exudation. It was this form which was usually met with in acute epidemics, but it might appear in the course of a number of diseases and be produced by a number of causes. Accompanying the process there might be more or less suppuration. Diphtheritic membrane being cast off, left irregular ulcers. Although ulceration was not a prominent feature usually, still it might be so extensive that only islands remain. In the more acute cases the inflammation extended to the peritoneum. This was the form found in eleven of the thirty-four cases. Among the eleven, other conditions present were: Chronic nephritis in four; acute nephritis in one; bronchitis and broncho-pneumonia in one; amyloid degeneration in one; cirrhosis of the liver in one; peritonitis in one; septicæmia in one; acute gastritis and enteritis in one. There was nothing in the anatomical lesions in the diphtheritic form by which one could distinguish the action of a definite pathogenetic agent.

The catarrhal form included cases which could not be made to come into the diphtheritic or amœbic forms. The name catarrhal had obviously been ill-chosen. These cases were characterized by an inflammation of the mucous surface leading to the production of shallow ulcers. Changes in the lymphoid cells were more common than in the other forms. It was really attended by abscess of the liver. Out of the thirty-four cases, fifteen belonged to the catarrhal class. Among complicating conditions were carcinoma of the stomach, phthisis, general paralysis of the insane, bronchitis, broncho-pneumonia, malarial fever, fatty degeneration of the heart and kidneys, etc. In but three of them was the dysentery chronic. Regarding the etiology of the catarrhal and diphtheritic forms we were still much in the dark. In the catarrhal,

the lesions were so various that it was impossible to believe they were all due to one cause. Klebs and others had described certain bacteria found in these forms, but that they were the specific cause had not yet been proven.

Amœbic dysentery was characterized by definite anatomical lesions and by a definite etiological factor. Eight of the thirty-four cases were of this kind. While the lesions varied somewhat, they all had something in common. There was generally a thickening due to an œdematous condition, circumscribed projecting nodules with small cavities filled with pus. The elevated nodules varied in size, and were situated in the sub-mucosa. The opening into them was frequently not larger than the head of a pin, or it might be so large that the whole cavity was exposed. The base of the ulcers was clean and formed by the muscular coat. The cellular infiltration extended through it into the sub-serous coat. The changes in the mucous membrane were for the most part secondary to those in the muscular coat. There was little change in the mucous membrane at a distance from the ulcers.

The author here passed to a description of the amœbæ which were found in the stools and intestines, sometimes in liver abscesses, etc. They might be in either the active or inactive state. They possessed two kinds of movement, the progressive and that limited to protrusion and retraction. As a rule, they were most numerous in the smallest ulcers where the process was most rapidly advancing. It seemed probable that they reached the submucous tissue, producing few lesions in the mucous membrane, this being attacked from below.

Abscess of the liver was present in seven of the cases. In four of them there was more than one abscess. In all the right lobe was affected, in two the left lobe also. Abscess of the lung was found in three cases, in two of which the diaphragm had been penetrated from the liver. The lesions produced by the amœbæ in the different organs were all of a kind. They caused necrosis and liquefaction of the cells and inter-cellular tissue.

There was no doubt but what amœbic dysentery was a widespread disease. Most of the cases, however, had occurred in tropical or sub-tropical regions, especially among Europeans visiting those regions.

Symptomatology. Complications and Treatment of Dysentery.—Dr. A. B. Ball, of New York, read a portion of an extensive paper on these subjects. Tormina and tenesmus were not, as had been claimed, always present in dysentery. Speaking of malarial complications, he said that they might undoubtedly exist, but disclaimed that the dysentery was due to the poison which produced the malaria. In tropical climates especially might the course of the dysentery be modified by malarial complications. The presence of joint complications had not been proven to be due to rheumatism or pyæmia. They were of the form which might be found in a variety of infectious diseases, and seemed to be due directly or indirectly to the primary affection. Dysenteric paralysis sometimes occurred in both the acute and chronic form. It usually lasted from three to twenty-eight days, and might be more or less distributed. Its cause had been claimed by some to be central, by some peripheral. Dr. Weir Mitchell had observed it in the hospitals during the war in a number of cases, and had stated that privation, bad food, and several conditions had existed as possible causes. Proper food and housing had in many caused so rapid disappearance of the paralytic symptoms, that he had been led to think it was possibly due to exhausted nerve functions.

Treatment of Dysentery.—Speaking of the treatment of dysentery, this had been variable, and he thought it not unlikely that the good results attributed to certain measures obtained in some cases and not in others might be accounted for by different etiology in the several forms. The ipecac treatment, which had originated in India about thirty years ago, had for some years received much support in that country, and to some extent elsewhere. Here, however, it had not obtained a strong foothold, which was to be accounted for partly by the depressing effects which the treatment produced in some cases, and partly to the fact that its advantages over other and less objectionable methods had not been proven. It seemed to be most successful in the dysentery of the tropics, and perhaps in the amœbic form. The opium treatment, which had been widely adopted in this country through the teachings of such men as Chapman, Flint, and Loomis, did not receive the author's warm endorsement. It had been claimed that the action of opium was not only astringent and anodyne, but that it also was antiphlogistic. Dr. Ball could not understand the reasoning on which this statement was based. One should not forget that disease could not be cured merely by suppression of its symptoms. Experience had taught him to more and more distrust the fallacious effects of opium in dysentery. Calomel seemed to have fallen into considerable disfavor, but he thought the reaction had probably gone too far, and that we were in danger of losing a valuable drug because of the misuse of it. Corrosive sublimate had been used and seemed to have a special tendency toward the colon, and perhaps rendered the soil unsuitable for the development of organisms. The author gave some space to a consideration of the irrigation method, which he thought was valuable. There was a possibility of producing fatal perforation by over-distention, though he did not consider this danger great. Speaking of the dietetic treatment, he said that in chronic dysentery he had found the use of meat of great value.

Treatment of Acute Dysentery by Antiseptic Colon and Rectal Irrigation.—Dr. W. W. Johnson, of Washington, read the paper. He advocated the local treatment of the disease based on the fact that the affection itself was local, confined to the colon and rectum. If the conditions present existed upon the outside of the body, no one would think of treating it except in one manner, namely, by the removal of the cause and the observance of cleanliness. If the mechanical difficulties could be overcome, there was no reason why the same treatment should not be applied with the disease situated in the bowel. The rationale of the method was shown in the fact that we had a local inflammatory process with rapid infiltration of tissues; a tendency to ulceration and necrosis, and extensive destruction; decomposition and retention of decomposing solids and fluids in the bowels would result in auto-infection; also the probable dependence of these conditions upon the introduction of a parasite. The author here briefly referred to the treatment of dysentery by cold and warm water irrigation and antiseptic irrigation. The early methods of antiseptic irrigation had been faulty, in that the fluid had been allowed to remain in the bowel for a greater or less period of time, and was liable therefore to cause poisoning. At present it was the custom to allow the water to flow out almost immediately, and without much distention of the bowel. He preferred to use two tubes of rather large size, Nos. 17 and 19 English, one for the introduction of the fluid, the other for its exit. A Davidson or Fountain syringe might be employed. In some cases simple rectal irrigation was sufficient, while in others the tube should be carried higher, if possible, even beyond the ileo-cæcal valve. While no doubt water could be injected beyond this valve, yet it was very difficult to pass the tube by it. Much force should be avoided, because of the danger of perforation at the seat of some ulcer. When the amount thrown in did not exceed the out flow, there need be no limit to the quantity used. The washing might take place once in three hours, less frequently when the discharges became diminished and had less odor, and there was less mucus. Relapses should be at once met with local treatment. The water might be plain or contain an antiseptic, be hot or cold.

A Contribution to the Study of Hepatic Abscess.—Dr. W. C. Dabney, of Virginia, read a portion of a paper

which he had prepared on this subject. Regarding the channels through which the bacteria or their products reached the liver, they might be the blood-vessels, the lymphatics, or the bile-ducts. Although the word pyæmia in connection with hepatic abscess has been used in two different senses, he recommended that it be restricted to its more ordinary meaning. He had not found any case in which the abscess had been clearly due to tubercular ulceration of the bowel. The ulceration of typhoid fever was not largely the source of abscess of the liver. In one of his cases there had been a history of typhoid fever three years before, with bowel trouble from time to time since; yet in this case the hepatic abscess contained amœbæ. In dysentery hepatic abscess might develop within two or three weeks, or not until a much later period. One could not set a definite period when the danger of hepatic abscess was over. A frequent origin of the abscesses was injury. He had found only three cases in the "Medical and Surgical History of the War of the Rebellion" which had been caused by a penetrating wound. Where the abscess formed after blows it usually took place within a few days—four to thirteen.

The usual seat of the abscess was in the right lobe, whether single or multiple, and oftener in the upper than in the lower part. Where the abscesses were multiple, the longer they lasted the more likely were they to break into one another; but the possibility of this occurrence did not justify delay in surgical treatment. He believed that the bursting of one abscess into another which had been opened was a comparatively frequent occurrence.

The contents of the abscess were sometimes so thick that they could not be withdrawn on aspiration. There was a sterile condition of the contents in a number of cases. Neither pain nor tenderness was conclusive evidence of adhesion. The symptoms of hepatic abscess, though usually well marked, were sometimes obscure or entirely absent. Their onset was usually gradual; sometimes sudden. Fever was usually present, but the temperature seldom went above 102° F. Jaundice was more frequent than was commonly supposed. He believed it was due to pressure on the bile ducts by adhesions, or to gall-stones. The condition of the bowels was of little value as an indication of hepatic abscess. Disturbance of the nervous system except for distention or pain in the region of the liver was rarely mentioned. Disturbance of respiration was rather common. Where albumin was present in the urine, it probably had no connection with the hepatic abscess. As to pain, sometimes it was quite steady, sometimes it came in paroxysms. Enlargement of the liver was usually present. Fluctuation had been mentioned in only 8 of the 108 cases which he had collected, and which he had made the basis of this paper.

Dr. Prentiss, of Washington, presented some large gall-stones, which had been passed by a woman who had given no other symptoms than those of pain in the intestines; evidently they had ulcerated into the intestine. Their passage had been followed by complete relief from the symptoms.

A Case Presenting the Symptoms of Landry's Paralysis, with Recovery.—Dr. F. T. Miles, of Baltimore, related the case. It occurred in a previously healthy man of good habits; commenced by a feeling of coolness and numbness in the lower extremities, extending upward until it had invaded the arms; at the same time there was gradual loss of muscular power from below upward. When he saw the man eleven days after the commencement of the symptoms there was complete paralysis of the limbs and great weakness of the muscles of the trunk and abdomen, sensation was apparently normal. The reflexes were completely lost, while the reaction to the faradic and galvanic currents was normal, the sphincters were absolutely intact. The facial nerve also became involved, and breathing became difficult. Having reached this point, the disease rapidly retrogressed, and by January 13th, a little over a month after the commencement of the attack, the patient was able to walk alone.

Dr. A. McPhedran, of Toronto, related a similar case. The illness began December 2, 1891, reached its maximum about December 20th, and by February 3d the patient was able to walk again. The electrical reaction in this case continued normal throughout; the paralysis of the extremities had been complete. The trunk and neck were also involved; speech was somewhat thick; swallowing slightly difficult; no trouble with breathing; bladder and rectum acted normally; knee-jerk absent.

Dr. Carey, of Buffalo, had seen a similar case, with recovery. In this instance the rectal sphincter was affected.

Dr. W. H. Thomson, of New York, had recently seen a case of Landry's paralysis in which at the post-mortem no evidence of peripheral disease was present. In another case still under observation the paralysis began in the left leg, extended to the right, to the lower part of the body, to the arms; caused great difficulty of respiration; no difficulty of deglutition, no bulbar symptoms; paralysis of the lower jaw. In fact the disease seemed to stop just short of involving the bulbar centres. The sphincters were not affected. The symptoms had in a large measure passed off. There had been no loss of electrical excitability, no atrophy, no sensory symptoms.

The Areas of Anæsthesia in Spinal Cord Lesions as a Guide to Localization.—Dr. M. A. Starr, of New York, read the paper. He said that it had been his good fortune the past two years to observe a number of patients suffering from disease in or about the lower half of the spinal cord who had presented disturbances of sensation. These, and others recorded in literature, formed a basis of some conclusions regarding the diagnostic value of such areas of anæsthesia. They went to show that a limited area of anæsthesia was produced by a limited lesion in the spinal cord; that, as the lesion extended from below upward, the area of anæsthesia extended upon the surface of the body, and that the extent and shape of the anæsthetic surface indicated the location of the lesion in the cord.

Of eighteen cases on which his conclusions were based, seven had occurred in his own practice; one in that of Rosenthal, one in that of Westphal, one in that of Oppenheim, Huber one, Bernhardt one, Osler one, Mills one, Herter one, Eulenberg two. Diagrams were shown illustrating the area of anæsthesia corresponding to the lesions, more especially in the sacral segments of the cord. An interesting case was that occurring in his practice in which the lesion was clearly in the upper lumbar portion of the spinal cord, causing complete anæsthesia from the waist down except over the buttocks and upper posterior portion of the thighs, corresponding to the sacral segments, showing that this portion of the cord had entirely escaped. The sphincters were usually involved together, and it was evident that their location was close together, and probably lay in the two lower sacral segments. In locomotor ataxia the disease began almost uniformly in the lumbar cord, not in the sacral cord, as shown by the fact that the disturbances of sensation were rarely referred to the buttocks. It was not until the first lumbar segment had become involved that the anæsthesia got as far up as on the abdomen. A study of the areas of hyperæsthesia confirmed the conclusions reached from a study of the areas of anæsthesia. Where the anæsthetic condition extended into the previously hyperæsthetic, it showed farther extension of the myelitis. A study of the anæsthesia alone did not offer much in differentiating between lesions of the cord and those of the cauda equina.

A Study of the Seasonal Relations of Corea and Rheumatism for a Period of Fifteen Years.—Dr. Morris J. Lewis, of Philadelphia, based this study upon the months of onset of 1,383 separate attacks of chorea, and 673 separate attacks of acute inflammatory rheumatism; 666 of the attacks of chorea occurred in Boston, and the remainder

in Philadelphia. The fewest attacks of chorea occurred in October and November. The greatest number in March and April. The greatest number of attacks of rheumatism occurred in April, the fewest in autumn. There was considerable resemblance in general form of the diagram tracings for the diseases in question to the tracings showing the number of storm-centres passing within four hundred miles of the two localities mentioned. Also, marked resemblance to tracings showing mean actual barometer and mean relative humidity. These facts tended to show that chorea and rheumatism were evidently seasonal diseases He regarded over-study as a predisposing, but not an exciting, cause of chorea.

Dr. M. Allen Starr, of New York, said that a study of 356 cases of chorea which had appeared at his clinic the past four years went to confirm the statements of Dr. Lewis. The attack in 34 occurred in March; 34 in May; the smallest number in the autumn. Fright had been attributed as the cause in 69 cases. The heart was found normal in 199. In eighteen per cent. there was a distinct history of rheumatism. There was an organic heart-murmur in 64; a functional murmur which subsequently disappeared in 56. He thought we had to look for different causes. The largest number of attacks occurred in the spring, because the existence of several factors culminated at that time in the greatest disturbance of nutrition.

Dr. Weir Mitchell said that in Philadelphia the patients with chorea appearing at the clinics were not from the lowest and poorest class, but rather from the mechanics and those above. It was a noticeable fact that chorea seldom occurred among the blacks, whose hygienic conditions were surely not always of the best.

Dr. Henry thought that Dr. Starr's statistics would indicate a greater proportion of cases of chorea depending upon rheumatism than eighteen per cent., for, as would be seen, they showed a large number of cases with heart lesion, which was in itself evidence of rheumatism.

Dr. A. Jacobi, of New York, said that there were many more cases of rheumatism in children than were diagnosticated. Growing pains were frequently of this nature. The latest statistics had shown the existence of rheumatism in about thirty per cent. of cases of chorea, and he thought that Dr. Starr's figures would, on analysis, be found to show about the same per cent. As has been suggested, the various conditions existing or surrounding children during the winter months tended to bring about that lowered state of nutrition which culminated in an attack of chorea in the spring.

Dr. Lyman, the President, made some remarks confirmatory of the view that chorea occurred oftenest among children with a tendency to the arthritic, the scrofulous, and other diatheses.

Dr. William H. Thomson thought the paper was a valuable one in helping us to get rid of fallacious causes of chorea. For instance, it was easy to draw out a history of fright by suggestive interrogations; yet, if this were a real cause, it must be that more children were frightened in the spring of the year than at any other time.

The Significance of Intermission in Functional Nervous Diseases.—Dr. William H. Thomson, of New York, read a paper upon this subject. The term functional had been applied to those nervous diseases in which no characteristic organic changes had yet been demonstrated. Most writers, however, regarded the term as only provisional, on the assumption that some kind of structural change in nervous matter must be the cause of every definite nervous disorder. Dr. Thomson challenged this view, which implied that it was necessary in some instances to look elsewhere than to the nervous system for either cause or remedy. The question, therefore, whether there were any distinctive features pointing to functional nervous diseases as opposed to those depending upon organic change in nervous structure, becomes of more than theoretical interest. He suspected that the main reason why all specific nervous disorders were ascribed to some corresponding derangement of nervous texture was, that every known organic nervous lesion was always accompanied by corresponding symptoms of functional derangement. This must necessarily be so. But this did not imply that derangements of nervous function must always depend upon derangement of nervous structure.

The first reason offered for drawing a distinction between the two classes was that in organic nervous disease the symptoms were always present, in the functional they were intermittent. Even grant that there might be diseases due to molecular, and therefore ultra-microscopic, changes in nervous matter, how would such changes explain intermission when molecular changes in every other case produced symptoms which were abiding as were those due to any other changes? Besides, no definite idea could be obtained from the molecular hypothesis.

There was always something plus mechanism (here the nervous system) needed for working, and that something was a source of energy (here the blood) which would work the mechanism. A lamp might be perfect as a piece of mechanism, but its function (to give light) would be imperfect if it were given oil mixed with water. The energy derived from the circulation caused the nervous system, glands, and other structures to work, and if this were faulty the work would be imperfect although the mechanism showed no molecular change. The blood was, he held, more than simply a nutritive and energizing fluid; it was a living tissue as well, owning a living birth and origin as much as the muscular and nervous tissues. It possessed hereditary faults of development as much as did nerve-fibre. If so, persistency of symptoms due thereto might be just as strong in the one as in the other. Were the distinctive features of neuroses, of which intermittency was one, best explained by the hypothesis of textural changes, or were they best connected with the more easily varied states of the functionating element of the living mechanism? He answered the latter, after, however, offering in argument the action of poisons, which showed intermittency and absence of appreciable structural change. These poisons might be drugs taken within, or such as were developed within the body, which modern chemistry had shown to be so numerous. These views applied to treatment would lead the physician to look for aid in the advancement of knowledge relating to the chemistry of diet. He should, in epilepsy, for example, look carefully for any evidence of perversions of gastro-intestinal function, or of secondary assimilation or excretion. Family histories of such perversions should especially be taken into account. Gastro-intestinal antiseptics should be studied as a particular branch of therapeutics. The value of a certain class of purgatives, conjoined with the administration of antiseptics, had been particularly impressed on his mind in the treatment of migraine, hysteria, and melancholia with quickened pulse. Lastly, investigation of leucomaines was of equal importance in a great variety of morbid states with functional disturbances.

Directed by these three principles, suggested by the progress of organic chemistry, he thought that our treatment of functional diseases would be much more effective than if we continued to seek for mere drugs with specific properties, or fruitlessly awaited the verdict of pathological anatomy.

A Collective Investigation in Regard to the Value of Quinine in Malarial Hæmaturia or Malarial Hæmoglobinuria.—Dr. H. A. Hare, of Philadelphia, read the paper. Of the replies received, chiefly from Southern physicians, he had been able to utilize one hundred and fifty-five. Fifty-four of these stated that malarial hæmaturia was seen frequently; fifty-one regarded it as most dangerous; very few as not dangerous. Some put the death-rate at twenty five per cent. Nineteen with experience stated that quinine in this condition was useful, twenty-eight as harmful, twenty-seven that they had seen it produce an attack.

The author said that bloody urine might occur in malaria in a number of different ways and in a variety of malarial affections, and went on to state those ways and conditions. Individual idiosyncrasy had much to do with it. This should especially be taken into consideration in treatment. Quinine, for instance, might or might not be useful according to the cause. There was no doubt but that this drug did cause blood to appear in the urine in some persons of hemorrhagic tendency. Malarial fever predisposed some persons to this influence of quinine. The necessity for caution was evident.

Dr. Atkinson had seen many cases of hæmaturia in malarial cases, but had not attributed it to quinine, which in many instances had been administered before the patients came under his observation; or, if this agent acted as an exciting cause, it was owing to individual idiosyncrasy.

Dr. Tyson thought quinine would prove a prophylactic in districts where malaria existed and was the cause of hæmaturia. If the quinine itself ever caused the bloody urine, it was owing to individual idiosyncrasy.

Dr. Stockton believed the hæmaturia could in many cases be controlled by large doses of alum—a gramme every hour—as advised by Dr. Didama.

Dr. Henry doubted whether other causes of the hæmaturia had been excluded before attributing it to quinine or even malaria.

Dr. Vaughan had seen a great many cases of malaria in Southern Illinois, Michigan, etc, but had not been able to trace it as a cause of blood in the urine, nor had he known quinine to cause hæmaturia. It followed that hæmaturia in malarial cases in the South must depend upon something else than quinine or the malarial plasmodium.

Dr. Loring had seen much of malaria in all parts of the East and Middle of the United States, also in the West Indies and South America, and had seen hæmaturia only in the South, seldom even there, never as caused by quinine.

Election of Officers.—Officers were elected as follows: *President*, A. L. Loomis, of New York; *Vice-President*, Reginald H. Fitz, of Boston; *Treasurer*, W. W. Johnston, of Washington; *Secretary*, Henry Hun, of Albany; *Recorder*, J. Minis Hays, of Philadelphia; *New Member of Council*, A. B. Ball, of New York.

Third Day, Thursday, May 26, 1892.

Misconceptions and Misnomers Revealed by Modern Gastric Research.—Dr. Charles G. Stockton, of Buffalo, read the paper. Reference was made to the condition described by Murchison twenty years ago, known as lithæmia. Growing out of that idea, a complete withdrawal of carbo-hydrates had been advised. From this point it was taught that meat constituted the proper diet for typical gout. But how was it that with the gouty meats disagreed in England and agreed in America? Observation taught him that the difference was due to a misconception; that gout was rare in America, while lithæmia, not meaning gouty diathesis, was here very common.

Wherever mental strain, "nerve tire," and imperfect oxygenation were seen, there was witnessed that group of phenomena that was here denominated lithæmia. He held this was not gout. Careful study of such cases showed the frequency of connection with digestion, and he believed such connection always existed. The condition was, then, a toxæmia of gastric origin.

The patients that did not digest meat well, had hypohydrochloric acid secretion; when, on the other hand, there was hyper-hydrochloric acid secretion the albuminoid often afforded immediate relief. Exercise, however, was also necessary. Neurasthenia, vertigo, persistent headache, muscular spasm, epileptiform convulsions, etc., were among conditions induced by gastro-intestinal toxæmia. A careful examination of the stomach was important in all cases.

The Production of Tubular Breathing in Consolidation and other Conditions of the Lungs.—Dr. Charles Cary, of Buffalo, in the first part of a paper bearing this title, presented the commonly accepted ideas regarding the cause of sound called bronchial, or tubular breathing. If these in part were not erroneous, they at least did not cover all of the causes. About three years ago, he had taken up, with a view to throwing light on obscure points on this subject, some experimentations believed to be original. Since then, however, he had learned that the same experiments had been carried out by others. They consisted in part in making metallic casts of the air-passages by pouring into the trachea an alloy which fused at a low temperature, 65° C. By this means he had obtained exact and durable casts of the trachea, larger and smaller bronchi. The surrounding lung-tissue was afterward eaten away by caustic potash. He particularly invited attention to the method of division of the bronchial tubes, which took place quite uniformly, and at the same angle. Also that the air reached the air-cells only after passing through a long route, varying its course at the different points of bifurcation. Furthermore, that at the points of bifurcation, there was a sharp edge to the bronchial tube which acted as a prow, cutting the column of air. It was to the blow at these points of division, that he attributed in a measure the so-called tubular breathing and the variations in pitch. This tubular blow would be induced whether the air was passing in or out of the lungs. There were modifying conditions, of course, as there were in the case of other sounds connected with breathing. If the tube, for instance, were partly filled with a secretion the pitch would be higher. He thought the reason why this explanation had not been offered before, was that the size of the tubes had been underestimated, as had also the acuteness of bifurcation. The other elements going to produce the bronchial, or tubular, breathing were the larynx and the trachea above.

Dr. Tyson thought that in a line with this explanation offered by Dr. Cary, the rhyma-glottidis had something to do with the production of the sound.

Dr. Mason mentioned adhesion.

The President, Dr. Hare, and others expressed their appreciation of the paper.

Different Forms of Cardiac Pain.—Dr. Samuel C. Chew, of Baltimore, opened his paper with the remark that cardiac pains were due to several affections which differed from one another both in nature and pathology. They were situated apparently, or actually, in the heart. We had no proper term by which to designate cardiac pain. The three divisions which he considered were true angina pectoris, which occurred in paroxysms, at first, at least, was accompanied by increased arterial tension, and was usually associated with aortic or coronary disease, or fatty degeneration of the heart. The pain was a peculiar one, being really something in addition to a pain, a feeling of impending death. Of two pathological conditions, coronary obstruction and fatty degeneration, we could only suspect their existence during life. Hence, the prognosis might be equally grave, whether an organic lesion of the heart was or was not recognized. Like in the other forms, it was difficult to determine the exact relation between the symptoms and the lesion. The immediate cause seemed to be neurotic. In this form he had obtained the greatest relief from the paroxysms by the nitrites, especially nitrite of amyl. Closely allied with this type was the cardiac pain associated with Bright's disease. Here the iodide of potassium in large doses might sometimes ultimately prove beneficial by lessening the arterial sclerosis. Nitrite of amyl again might relieve the pain. The third form considered occurred in dilatation of the heart, and it had been attributed to stretching and pressure upon the nerves. One of the best tonics was arsenic.

Dr. M. A. Starr, of New York, mentioned two other classes of cardiac pain, namely, that occurring in connection with paroxysmal tachycardia, and the other in

what he had termed the vasomotor type of neurasthenia. He also referred to Nothnagel's article showing that the statement usually made, that cardiac disease was unaccompanied by pain, was an error.

Dr. Musser, of Philadelphia, insisted upon rest and careful attention to diet.

Dr. McPhedran had found nitro-glycerine preferable to nitrite of amyl, and said its effects were more lasting.

Dr. Stockton had often found cardiac dilatation at autopsy in which there had been no history of cardiac pain.

Dr. Chew thought that nitro-glycerine was useful for preventing attacks, but not for relieving them after they had come on.

Dr. Stockton related a case in which large doses of nitro-glycerine (half-grain) relieved the paroxysm, while nitrite of amyl failed.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE LUMLEIAN LECTURES AT THE ROYAL COLLEGE OF PHYSICIANS—SOME CURRENT OPINIONS TRAVERSED—DISCUSSION ON RENAL DROPSY AT THE MEDICAL AND CHIRURGICAL SOCIETY—SPEECHES BY DRS. W. H. DICKINSON, GEORGE JOHNSON, AND PYE SMITH—SIR JAMES CRICHTON-BROWNE ON SEX IN EDUCATION—THE MORTON LECTURE ON CANCER—THE ROYAL COMMISSION ON GRESHAM UNIVERSITY FOR LONDON—INFLUENZA.

London, April 30, 1892.

In the "Lumleian Lectures" recently delivered at the College of Physicians, Dr. Pye Smith selected as his subject "Certain Points in the Etiology of Disease." A wide field was reviewed by the lecturer. On several subjects he enunciated views somewhat at variance with those generally accepted. Thus he suggested that there was hardly adequate evidence for the common belief that bronchitis, pneumonia, or pleurisy followed the application of cold to the chest, and that enteritis or peritonitis was produced by cold on the abdomen, or nephritis by cold upon the loins. He expressed himself as sceptical with regard to the value of applying ice to the chest in hæmoptysis, and said he did not believe that such an application could check pneumonia. He sarcastically remarked that it would scarcely be held by the same physician that pneumonia was both caused and cured by cold applied to the chest. Speaking of the group of diseases which have their origin in physiological disturbance gradually becoming more frequent, ending in permanent structural disease, he remarked that we had always to bear in mind that "it takes two to make a quarrel." It took two to produce a disease—the blow and the reaction, the irritant and the patient. When a man complained that wholesome food disagreed with his stomach, we might retort that his stomach disagreed with his food. The lecturer said he had learned from Dr. Wilks an important point in the etiology of (most) diseases, viz., that acute diseases were often developed out of chronic. Probably the only maladies in which the onset was often sudden were those which were contagious and depended upon the invasion of a healthy organism by a countless swarm of foreign organisms attacking it from without. Even in the case of infective diseases, however, experimental pathology taught us that, while on the one hand an organism might be rendered refractory to the invasion of the virus, on the other hand it might be artificially prepared so that the subsequent invasion of a very attenuated virus would produce the most severe effects. The injection of the cultivation fluid of blue pus was an example of this. It was a matter of common experience that enteric fever often began with certain days, or even weeks, of diarrhœa, and might it not be that the local conditions of the intestines rendered them more obnoxious to the action of the contagion when it invaded? Genuine diphtheria was often preceded by non-specific and subacute angina.

Several other examples of predisposing conditions were mentioned by the lecturer. He protested against the use of the terms "diathesis," "dyscrasia," and "temperament," as unscientific and prejudicial to the advance of etiology. To say that a man who had had rheumatic fever had a disposition to its recurrence was only to say that rheumatism was a disease which usually occurred more than once in the same person. If a man's father had had phthisis or gout, he was, no doubt, predisposed to those diseases, but this was only saying that phthisis and gout were often hereditary. The disposition of tendency for these or other diseases was either carried out or it was not. If it was never carried out, its existence could not be proved and was of no practical importance; if it was carried out, the right way to put the fact was to say that the disease occurred, and the supposed predisposition to it was only a roundabout way of repeating the assertion.

Discussing the etiological influence of sex, Dr. Pye Smith observed that two important diseases had been asserted to be etiologically related to sex which were, he believed, really indifferent in that respect, viz., gastric ulcer and progressive pernicious anæmia. Of 93 cases of the former disease in Guy's Hospital which went out relieved or cured, 33 were men and 60 women; of 101 cases which died in hospital 59 were men and only 42 women. Excluding secondary and spurious cases, and keeping to Addison's original and masterly account of the disease, we should find that progressive pernicious anæmia was as common among men as women. This agreed with its true pathology, for it was quite distinct from chlorosis, and was naturally allied with the other essential and grave forms of bloodlessness which we knew as leukæmia and Hodgkin's disease, all of which were more common in the male than the female sex, and all of which were unbenefited by steel, but sometimes cured and often relieved by arsenic. Dr. Pye Smith expressed his disbelief as to the evil effects of overwork, and said that, excluding certain definite lesions, there was no evidence that harm was done, disease brought on, or life shortened by what was commonly known as work—whether mental, physical, or a combination of the two. He also protested against the assumption that this nineteenth century was fuller than any other of "worry" and anxiety.

Referring to the assertion that gout and phthisis were prophylactic against each other, the lecturer said he thought this was an error. He had observed their conjunction more than once; that they did not often coincide was to be expected from their incidence on different periods of life. A similar criticism would apply to the presumed opposition between tubercular and malignant disease. Carcinoma mostly affected elderly persons, while the majority of phthisical patients were young adults. Children with tubercle died before they could develop sarcoma, children with sarcoma died before they could develop tubercle, and adults affected with tubercle too often died before the age at which cancer was most frequent. In a patient of his own, aged fifty-eight, who had died from cancer of the stomach, both old and recent tubercles were found in the lungs.

At the last meeting of the Medical and Chirurgical Society a discussion on "Renal Dropsy" was opened by Dr. W. H. Dickinson in an elaborate paper. Dropsy fluids, he said, varied in composition more according to their position than their cause. Thus effusions in the serous cavities were always albuminous. If the albumin were the issue of filtration and pressure, these agencies were active in dropsy of every origin; if the salts present were evidence of osmosis this process was much the same in all. He did not think osmosis, alone was sufficient to account for dropsy—whether renal or otherwise. In ob-

structive suppression of urine where cardiac failure was obvious, and low arterial pressure inferred, though urine might be totally absent, dropsy might be equally so. In nephritis dropsy was early and well marked, and accompanied by increase of arterial pressure. With a further increase of arterial pressure, as the disease became chronic and cardio vascular changes were established, there was diminution of dropsy. Dr. Dickinson maintained that the cardio vascular changes of advancing renal disease were antagonistic to dropsy, and pointed out that when the heart finally gave way, mitral regurgitation, pulmonary apoplexy, and increase of dropsy resulted. The relation between dropsy and uræmia was not simple, for the most extreme uræmia sometimes existed while dropsy was totally absent. Anæmia had no necessary connection with dropsy, though often associated with it. The relation of hydræmia to dropsy was also complex. Water had been injected into the vessels of an animal without producing œdema. Slight dropsy resulted from the introduction of a large quantity of saline fluid into the veins of a diabetic patient, but there was reason to believe that the effect was due rather to increase of intravascular pressure than to simple hydræmia. With the increased arterial pressure of nephritis, though neither the anæmia nor the hydræmia was as extreme as in other conditions, dropsy presented itself, and Dr. Dickinson urged that the process was due to some change in the capillaries produced by the state of the blood, of which obstruction and transudation were consequences What the nature of the obstruction was must be left undeclared, but changes in the blood might affect its passage in many ways; the capillaries, though not muscular, had been demonstrated to be contractile. In chronic disease and the granular kidney the diminution of dropsy with the further increase of arterial tension required explanation. He suggested that the thickening and narrowing of the smaller arteries must cut off the blood from the capillaries, and presumably lessen pressure in them and exudation from them. The thickening of the ventricle must also increase its expansile power and suction action, and thus draw upon the pulmonary circulation and relieve the veins and interstices. Next came the beginning of the end in the yielding of the ventricle, regurgitation, increase of dropsy, and often pulmonary apoplexy. Putting aside lardaceous disease, the points of resemblance and of difference between renal and cardiac dropsy came into prominence. In both the accumulation was essentially what exuded from the capillaries and constituted the lymph. Under heart disease there was diminished absorption without any presumption of increased exudation, or not to any important extent; under kidney disease there was increased exudation without any necessary or constant diminution of absorption. Both were essentially connected with modifications of blood pressure; in one from obvious obstruction to the venous return, in the other from some presumably obstructive condition of the capillaries, which was attended with enhanced exudation from them, and associated with increased pressure within the arterial system.

Dr. George Johnson said he believed that in Bright's disease the seat of obstruction was in the arterioles—not in the capillaries. The phenomena observed when asphyxia was artificially induced threw much light upon the function of the arterioles. In some papers in *The Lancet* for April 4 and 11, 1891, he had adduced evidence of the power of the arterioles to impede the movements of blood, and he knew of no evidence to prove that a like power resided in the capillaries. Even if it were admitted that the capillaries had some power of contraction, that of itself would not explain dropsy through their walls, for the flow through them would be lessened. He believed that renal dropsy was an active, vital, secreting process, exerted by the epithelium of the vessels themselves, and brought into action by the accumulation of noxious substances in the blood. Cardiac dropsy also should not be considered a mere process of mechanical filtration, and the same applied to the anasarca of granular kidney. The pulmonary apoplexies common in the last stages of renal disease were caused by hemorrhage into a bronchial tube.

Dr. Pye Smith said he agreed with Dr. Dickinson in regarding cardiac dropsy as entirely due to difference of pressure. In obstructive cardiac disease there was increased pressure in the small veins and capillaries, and difficult entry of lymph from the main duct into the great veins. In renal disease there were two separate dropsies, viz., 1, early and especially renal, and, 2, that seen in the later stages of granular kidney. This later dropsy was "hydraulic" in character, and occurred when dilatation supervened on cardiac hypertrophy. The early renal dropsy was not capable of a similar explanation, and Heidenhain's recent experiments demonstrated the possibility of its connection with the secreting power of the capillary endothelium, though this had not yet been proved. The evidence was entirely against its being hydraulic, and Dr. Pye Smith thought it was probably not a dropsy at all, but an inflammatory effusion, the results of an active inflammatory change in the connective tissues affected.

The discussion was adjourned till the next meeting of the Society.

London, May 7, 1892.

Two noteworthy addresses have been delivered during the present week. The first of these was on "Sex in Education," by Sir James Crichton-Browne, who selected this as the subject of the annual oration at the Medical Society of London, which he was appointed to deliver. The orator maintained that the growing tendency around us to ignore intellectual distinctions between the sexes is unphysiological, and he adduced numerous interesting facts in support of this view. The radical explanation of sex, he said, was to be sought in what Michael Foster had called "the protoplasmic movement," that is to say, in the integrative and disintegrative changes of living matter. Anabolic and katabolic processes were manifold, varied in their relative ascendency in different individuals, and were influenced by environment, so that in tracing their operation through the animal kingdom, qualifications and explanations were from time to time needful, but subject to these it was everywhere obvious that the female was the outcome and expression of predominant anabolism, and the male of predominant katabolism. A study of the organic and functional, primary and secondary sexual characters, of the normal development of the tissues, and of their pathological modifications, made this evident, and a study of the emotional and intellectual characteristics of men and women led to the same conclusion. Differences in intellect implied cerebral differences, and first among cerebral differences between the sexes he would refer to mass and weight. Tables were produced showing that, allowing for differences of stature, there was still an excess of brain weight of more than an ounce in favor of the male. It could also be shown from the tables that organic diseases, and the atrophic changes they induced, lowered the normal difference between the male and female brain. That the smaller size of the female brain was a fundamental sexual distinction was made clear by the fact that the same difference in brain weight between men and women had been found in savage races. Not only was the male brain heavier than the female, but it had a wider range of variation in weight. There were also grounds for believing that there was a difference in the balance of parts in the male and female brains respectively. Broca had declared that the occipital lobes were more voluminous in the female, and Sir James Crichton-Browne said that his own observations confirmed this conclusion, and showed that, while the frontal lobes were equally developed in both sexes, the parietal lobes, which corresponded roughly with the motor area of Ferrier, were larger in the male than in

the female, and the occipital lobes, certainly sensory in their functions, were larger in the female than in the male. The third brain difference between the sexes was one of convolutional arrangement; mere ocular inspection would bring home to anyone who diligently used it the superior symmetry of the female brain, due to its comparative poverty in secondary gyri. He had also found the specific gravity of the gray matter generally lower in the female than in the male brain. Another momentous difference was in vascular supply. In an investigation carried on jointly with Dr. Sidney Martin, he had found that the diameter of the internal carotid and vertebral arteries, taken together, was slightly greater in the male than in the female. When the smaller size of the female brain was taken into account, it appeared that the female brain received a larger supply of blood in proportion to its mass than the male brain did, but it must be remembered that the blood was somewhat poorer in quality than that going to the male brain. The distribution of blood to the brain in the two sexes differed considerably. The internal carotid arteries, with their great branches, the anterior and middle cerebral arteries, supplying the supra-orbital convolutions and island of Reil, the gyrus fornicatus, the Rolandic area, the angular gyrus, and the first temporo-sphenoidal lobules were much larger in the male than in the female brain, but the vertebral arteries which supplied the occipital and temporo-sphenoidal lobules were larger in the female, and the basilar artery, which was practically a continuation of the vertebrals, was also larger in the female brain. The posterior communicating arteries were incapable of adjusting the balance between the direct currents of the carotid and vertebral arteries, and the result of the difference mentioned was that the anterior region of the brain was comparatively more copiously irrigated with blood in men, and the posterior in women. The region of the brain which in men was most richly flushed with blood was that which was concerned, we had reason to believe, in volition, cognition, and ideo-muscular processes; while the region which in women was most vascular was that which was mainly concerned in sensory functions, and we thus saw that there was a relation between the size of the cerebral arteries and what observation had taught us as to the intellectual and emotional differences of the sexes. Differences in brain structure and function had a special pathological significance at the period when sexual divergence was taking place most rapidly, and when education was being pushed forward with most vigor. The orator then proceeded to speak of the methods of education. He said he did not hesitate to affirm that overpressure was rampant in high schools for girls in this country, though there were those who believed that it was a medical myth. He protested against home evening lessons, and also against girls proceeding to school without having first had an adequate morning meal. He quoted in conclusion, as an argument against the equal education of the sexes, the remark that "what was decided among the prehistoric protozoa cannot be annulled by Act of Parliament," and he said that the essential difference between male and female could not be obliterated at a sweep of the pen by any Senatus Academicus.

The "Morton Lecture" on Cancer and Cancerous Diseases was delivered at the College of Surgeons on Thursday last, by Dr. Sims Woodhead. He said that what he had to say might be arranged under three heads: 1. The conditions within the tissues that may predispose to cancer; 2, what we know as to the nature of the irritants that are now assumed to play a specific etiological part in the production of cancer; 3, what is to be gathered in respect to the treatment of cancer from recent researches on the subject. Speaking on the first of these heads, Dr. Woodhead remarked that at one period of life the connective-tissue cells were most active, at another the epithelial cells. So far as concerned our tissues, we might come into the world middle-aged men and women. Only premature senescence could account for many of the anomalous conditions that made their appearance in the practice of the surgeon. We now accepted it as a well authenticated fact that by varying the conditions of nutrition, the facilties for excretion, and the nature and amount of stimulation or irritation, we could, to a certain extent, control or alter the character of the cells produced by a given set of tissues; we had an admirable example of this in cartilage and tendon. Dr. Woodhead said he believed at one time, and still thought it possible, though, perhaps, scarcely proved, that if cells were formed generation after generation under the action of an irritant, their specialization might be gradually interfered with, a less and less irritant being sufficient to keep up the new form of cell, until eventually the acquired form might become more or less permanent. This might serve well enough as a working hypothesis were we still unaware of the fact that in almost every other department of pathology some specific irritant, which was capable of exciting the changes set up in specific processes, was present. Why did we get the age distribution of tumors that was insisted on, now many years ago, by Virchow and Paget? Might it not be that similar stimulating or irritating agents were capable of giving rise at different periods of life to these different forms of tumor, and that the essential difference consisted in the different nutrient and developmental conditions of the tissues. He had long been of opinion that in classifying cancers and epitheliomas the age of the patient was not the only factor to be taken into account; the organ affected must also be considered. The lecturer then adverted to an investigation which he had made as to the condition of the epithelium of the tongue at different ages He discussed at some length the structural peculiarities of the investing epithelium taken from a definite point at different periods of life, and insisted upon the importance of these differences in connection with the etiology of cancerous growths.

It must be accepted for the present, said Dr. Woodhead, that malignant tumors were to be looked upon as overgrowths of certain tissues started into activity by some unknown cause. What could be the exciting cause? It was necessary that there should be a continuous irritation, and one capable of multiplication. Hitherto few irritants had been found capable of keeping up continuous irritation for any length of time, and such as had been met with were confined almost entirely to those vegetable parasites which specially affected the connective tissues. Up to the present, comparatively few parasitic vegetable organisms had been found that had the faculty of living in any of the active epithelial cells of an animal; these cells were usually described as offering a most determined resistance to the entrance of most vegetable micro-organisms. Numerous observers had thought they had succeeded in demonstrating the presence of specific vegetable micro-organisms in epithelial growths; but these, in most cases, had been proved to be merely common saprophytic organisms. Dr. Woodhead then referred to the controversy respecting the organism known under the name of "coccidium," which occurred in the liver of the rabbit, and which was known to set up a peculiar irritated condition of the bile-ducts, which ended in the formation of psorosperm nodules. One could not but be struck by the very marked similarity between psorosperm nodules and cancerous growths. The so called fuchsin bodies found by Russell were then referred to. The lecturer concluded, however, that we were very far from having proof that these bodies were the actual cause of cancer. Why should they make themselves felt only under certain conditions, and at certain periods of life? He remarked that a coccidial theory of cancer, if proved, would render it necessary that we should throw aside the doctrine that cancerous epithelium could be developed from anything but epithelial cells.

In regard to treatment, the lecturer favored free removal of the tissues. He said he firmly believed that

those surgeons were in the right who maintained that the only safe rule to be observed in removing cancer of the breast was to remove, not only the main mass of the gland, but all outlying portions of glandular tissue, both laterally and in depth, so that if, on cutting away the margins of the tumor, treating with nitric acid in methylated spirit (five per cent.), and then with water, any opaque columns or fragments were still to be seen, he should consider that the removal had not been free enough.

Considerable dissatisfaction has been expressed at the constitution of the Royal Commission on the proposed Gresham University.

Influenza has not yet disappeared entirely, and eight deaths from it within the metropolitan area were registered last week.

SENN'S HYDROGEN TEST.

To the Editor of the Medical Record.

Sir: Relative to a point of objection against the Senn hydrogen test for intestinal perforation, that of a possible explosion within the belly when the torch is applied to the tube, urged frequently by Dawbarn, and recently in a paper by him before the New York Academy of Medicine (February 8th), I desire to say a few words.

Being some years ago a member of a class before whom Dr. Dawbarn demonstrated the Senn test on the cadaver, I heard from him this objection. As the gas began escaping from the tube, I inverted over it a drinking-glass. Hydrogen being lighter than air, at once displaced the air and filled the glass; removing this, still inverted, a short distance from the body, a match was applied and the gas ignited, a perfectly safe method of demonstrating the escape of hydrogen from the tube.

The object-lesson seems to have been lost upon my good friend Dr. Dawbarn, who still urges the danger of explosion within the cavity.

PLAGIARISM EXTRAORDINARY.

To the Editor of the Medical Record.

Sir: I desire to call your attention to an article in the *Journal of the American Medical Association* for May 21, 1892, by Dr. Hal Foster, of Kansas City, Mo., on "How a General Practitioner may Treat Atrophic Rhinitis," said to have been read before the Kansas State Medical Society, at Fort Scott, Kan., on May 4, 1891 (*sic*). Such an article, under the title "The Etiology and Treatment of Atrophic Rhinitis," by Jonathan Wright, M.D., of Brooklyn, appeared in the Medical Record for August 15, 1891, having been read by the author before the New York Kings County Medical Association on May 12, 1891. That article was given to the typewriter prior to May 2, 1891, and returned to the author's house on May 7, 1891. The author was absent in Baltimore and Washington from May 2 to May 9, 1891, and found the article awaiting him on his return. Some time in the fall of 1891 a person signing himself Dr. Hal Foster, of Kansas City, wrote to Dr. Jonathan Wright asking him for reprints of some of his articles. They were sent to Dr. Foster. (The writer states the last two sentences from memory alone, and may be mistaken. There is documentary evidence to support what preceded.)

The paper in the *Journal of the American Medical Association* of May 21, 1892, is practically a verbatim copy of the paper in the Record for August 15, 1891. Consequently this is a matter which vitally affects the personal and professional reputation of at least one of your contributors, because the *Journal* paper purports to have been read May 4, 1891, while the Record paper was read May 12, 1891.

According to the announcement in the Record (advt., p. 15), the Kansas State Medical Society met at Fort Scott, Kan., on May 3, 1892.

We are accustomed to plagiarism in these days, but wholesale theft of a paper word for word (with exception of a few lines) is surely somewhat of a novelty.

Who was the offending party in this case, I leave to your impartial investigation, and remain,

Very truly yours,

Jonathan Wright, M.D.

73 Remsen Street, Brooklyn, N. Y.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending May 28, 1892.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	4	8
Scarlet fever	183	33
Cerebro-spinal meningitis	1	4
Measles	749	36
Diphtheria	95	35
Small-pox	13	3
Varicella	0	0
Pertussis	0	0
Erysipelas	0	0
Leprosy	0	0
Mumps	0	0

The Danger of Celluloid Buttons.—Professor C. Vernon Boys, of England, reports the case of a lady, standing near a bright fire, who suddenly found herself enveloped in smoke. A gentleman who came to her rescue succeeded in crushing the ignited portion of her dress, not, however, without severely burning his hand. On investigation the fire was found to have originated from a spot where a large fancy button had been, but had disappeared. Similar buttons were subsequently examined, and were found to be highly inflammable, being made of celluloid.

Suppression of the Thesis in France.—The question of doing away with the doctorate thesis in the French medical schools is being warmly discussed by the journals. The grounds upon which the change is advocated are that the printing of a long thesis is expensive, and is often a serious tax on the limited resources of the student; that it affords no evidence of the student's knowledge, and finally, that it is usually a very poor production in a scientific, if not in a literary, sense.

The Seutin Prize.—The Seutin prize of 5,000 francs, for 1890–91, offered by the Brussels Royal Society of Medical and Natural Sciences for the best essay on "The Etiology, Diagnosis, and Treatment of Inflammations of the Fallopian Tube," has been awarded to Dr. Theodore Landau, of Berlin.

Some of the Subjects of the "Bichloride-of-Gold" Treatment.—Colonel Mines, a few weeks after his "cure," died of alcoholism. James G. Fair died of heart disease directly attributed to the treatment. Walter R. Earle died a raving maniac a week after his dismissal. Henry Anstey died during treatment. Luther Benson went mad. Charles Vaughn went insane. Ex-Congressman Hopkins went mad, and died soon after treatment. —Dr. Charles H. Merz, in the *Medical Age*.

PRACTICAL POINTS IN THE TREATMENT OF CLUB FOOT.[1]

BY A. B. JUDSON, M.D.,
NEW YORK.

THE treatment of congenital club-foot is a subject doubtless as old as the hills, and yet ever new, since the correct method of treatment is apparently as far as ever from being well established and unanimously accepted. I cannot hope to do, this evening, what so many experimenters in so many years have not done, but will present some thoughts which may, on the one hand, assist the practitioner burdened with such a case, and, on the other hand, relieve some beginner from the false notion that a rapid and brilliant success is within his reach in cases of this kind.

I will limit myself to emphasizing two, and perhaps three, points of practical interest. It is well to bear in

FIG. 1.

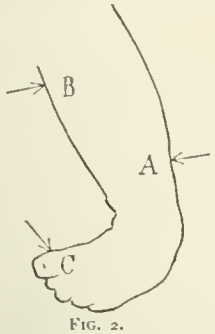

FIG. 2.

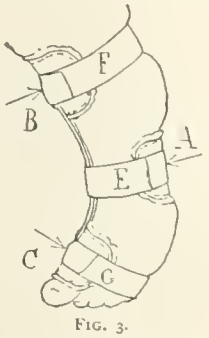

FIG. 3.

mind, to begin with, that there is a vast difference in such a case between a child walking and a child recumbent. When the baby is in arms the case is still uncomplicated by the weight of the body thrown on the deformed foot. And this is the first practical point in the treatment of this affection which I would emphasize, and would repeat as follows: While the child is in arms, and the case is yet free from the complications and difficulties caused by the falling of the weight of the body on the deformed foot, the case should receive the most assiduous and persistent attention. These twelve months, more or less, are the most important year in the history of the case, because in this interval the foot is to be so changed that when the child becomes active on his feet the application of a slight walking-brace, exerting only a moderate degree of force, will convert the weight of the body from a deforming to a correcting force. During these months of recumbency, with the weight of the body out of the way, with all the tissues comparatively soft and formative, and the foot more than doubling in size with the growth of the child, there is every reason to expect to succeed in what we undertake, provided time enough be given to the case, and faithful attention to the details.

The agent used to effect this partial reduction before the child learns to stand is a simple retentive splint, which acts as a lever, making pressure at A, in Figs. 2 and 3, on the outer side of the leg and foot, on the convexity of the deformity, and counter-pressure at two points, one on the inner side of the leg, below the knee, at B, and the other on the inner border of the foot at C. The fact that this simple instrument is a lever is the second practical point which I would emphasize, because if we know that we are making use of a lever, with its well-defined three points of pressure, or rather one point of pressure, A, and two of counter-pressure, B and C, we can get more out of the apparatus than if we view it in a more indefinite way, as an application for improving the shape of the foot and leg. I use a little brace made of sheet brass, doing the work with a few simple tools. One advantage of doing the work yourself is that you know whom to blame if the work is not properly done. Two curved disks, B and C, in Figs. 4, 5, and 6, of thin brass, are riveted to the ends of a narrower and thicker piece, D, to form the part of the brace which makes the two points of counter-pressure. A third disk, or shield, A, in Figs. 4, 5, and 6, is applied to the convexity of the deformity with a strap of adhesive plaster, E, in Fig. 3, surrounding the leg, and including the shield and the piece which connects the two disks. All the disks are to be lined with pieces of blanketing easily renewed. These braces are so cheap and easily knocked together that it is nothing to apply new and larger ones, using heavier materials as the child grows.

The brace is applied with three narrow straps of adhesive plaster. The upper and lower straps, F and G, in Fig. 3, are simply to keep the apparatus in place, while, by drawing the middle strap, E, tightly over the shield, and straightening the brace from time to time, the deformity is gradually and slowly reduced. At each reapplication the brace is to be made a little straighter than the foot and leg at that stage. This may readily be done by the hands, and then the middle strap is to be tightened over the shield till the shape of the limb agrees with that of the brace. After a few days the brace is to be made still more straight, and again reapplied and made tight till another point of improvement is gained.

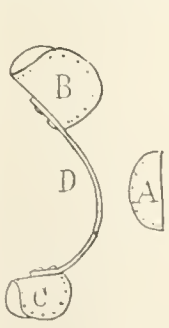

FIG. 4.

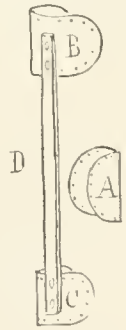

FIG. 5.

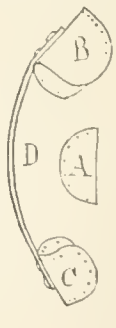

FIG. 6.

The brace is applied very crooked at the beginning of treatment, as in Fig. 4, and is straightened from time to time, and a larger brace applied as the deformity is reduced and the patient grows. It may be removed every week or so, and an interval of a few days allowed for freedom from the brace, when the mother is directed to manipulate the foot, using as much force as she will in the direction of symmetry.

By this simple and prosy treatment, carried out systematically and without haste, or violence, or pain, the foot, unless it is a frightful exception, may with certainty be changed from varus to valgus. Fig. 4 shows approximately the shape of the brace at the beginning of treatment, Fig. 5 when the varus is reduced, and Fig.

[1] Read before the New York County Medical Association, May 16, 1892.

6 when valgus has taken the place of varus. The foot in this latter stage may not hold itself valgus when left to itself, but with almost no force, and with one finger, it may be pushed into valgus, and in this condition it must be when the child begins to walk, and then an entirely new phase of treatment begins.

The brace useful to this point is now useless, because it cannot hold the foot against the overpowering weight of the child when he stands, and yet, with no brace at all, every step made with the outer border of the foot on the floor is a force perpetuating and increasing the deformity. Here it has been noticed that there is an important boundary line between deformity and symmetry. If the foot is held in some way on the right side of this line, each step forces it in the direction of valgus, and the increasing weight of the child is a powerful force, acting in the right direction so long as the foot is held, though never so little, looking toward symmetry. It may be said that the child stamps himself straight. If, on the other hand, the foot is held, or allowed to go, on the wrong side of this line, though never so little, each footstep is a blow driving the foot more and more into the varus position. And this is the third point which I would especially emphasize. From the time the child begins to stand, the weight of the body should be made to act against, instead of in favor of, the deformity. This may be done by mechanically holding the foot in a proper position to receive the weight pressing down from above. If this is not done, standing and walking will increase the deformity.

The brace needed from this time on must be made of steel by an instrument-maker. Like the one which is used in the beginning of treatment, one of its functions is to act as a lever against the deformity, but the leverage now used is not so much to overcome the deformity directly, which cannot be undertaken with success against the weight of the body. The force of the lever is now applied to hold the foot on the right side of the boundary line above mentioned, so that the weight of the body straightens the foot in a direct and forcible manner.

The brace used at this stage consists of the ordinary foot-piece and upright, with a transverse band at the upper part. The band is placed behind in order to give attachment to a piece of webbing which crosses the front of the leg. The upright is on the inner side of the leg. The upright is to be bent from time to time as the foot improves. This and other parts of the brace should be made of mild steel, to facilitate alterations in shape and the shifting of buckles and straps as required, all of which may be done by the use of a few simple tools. The foot-piece, riveted to the upright, has the usual riser on the inner side of the foot, to which is riveted an ear made of sheet brass to keep the great toe down, and a spur projecting upward from the back part of the outer border of the tread to give attachment to one end of a piece of webbing which makes the heel-cup, the other end of the webbing being riveted to the lower part of the upright. The foot-piece is lined with adhesive plaster to prevent rust, and with a piece of truss leather fastened with two rivets. In practice the details demand as much attention as the principles of treatment. The brace is worn over the stocking and under the shoe, while the moderate pressure necessary is made by buckles and pieces of webbing.

Besides keeping the foot in proper position to receive the weight of the body, I may mention two or three other advantages to be derived from the use of this brace. For instance, a narrow strap of adhesive plaster wound around the foot and buckled to the riser of the foot-piece rotates the sole of the foot outward and combats the varus. Again, as the deformity is reduced and the upright is bent, the tread of the foot-piece becomes an inclined plane, higher on the outer border and lower on the inner border of the foot, the effect of which is to combat the varus by rotating the sole of the foot outward. Furthermore, the addition of a strap making pressure backward at the upper part of the leg transfers to this point some of the pressure which would otherwise be received, when the patient walks, on the anterior part of the sole of the foot, thus facilitating the correction of the varus, and making it possible at a later stage of treatment to stretch the tendo Achillis by gradually reducing the obtuse angle which is made at first between the upright and the foot-piece.

As the child outgrows this walking brace a larger one is to be made, and when three or four years old the foot will, without the help of the brace, strike the ground so fairly that, for two or three years, all treatment may be suspended. The patient is to be observed from time to time, however, and as the foot grows in its original inclination to varus, it will, after the lapse of two or three years more, have to be kept in proper position under the rapidly increasing weight of the body by a brace similar to the last for another period of two or three years. When the foot is full grown it will be normal and shapely in appearance when dressed, and practically perfect in its ability to perform all the functions of a foot congenitally normal. While the foot is under treatment in this way the improvement is continuous, and the natural and obvious result of the means used, considerations which bespeak and retain the confidence of the parents of a child thus affected, a practical point, in closing, not to be overlooked in cases which occupy so much time in treatment.

ON ACHYLIA GASTRICA.*

By MAX EINHORN, M.D.,

INSTRUCTOR IN CLINICAL MEDICINE AT THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND PHYSICIAN TO THE GERMAN DISPENSARY, NEW YORK.

Achylia † gastrica (lack of gastric juice) forms the main symptom of the affection heretofore described under the heading of "Atrophy of the Stomach."

Whereas in most diseases we first mapped out the clinical picture and found the pathologio anatomical condition much later, in the disease in question—"Atrophy of the Stomach"—the course of things was quite the reverse. First we found, at autopsies, stomachs with atrophied glands (Fenwick,[1] Lewy,[2] Ewald,[3] Kinnicutt[4]); later the clinical appearances corresponding to these conditions during life were described and really found.

One of the most elaborate papers on this subject is that of George Meyer,[5] entitled "Zur Kenntniss der sogenannten Magenatrophie" (To the knowledge of the so-called "Atrophy of the Stomach"). I may be allowed to desist from going into a description of the literature of this subject, as this can be found in all its details in the aforementioned paper of Meyer.

The clinical appearance of the cases of atrophy of the stomach, described first by S. Fenwick, later on by Osler,[6] Nothnagel,[7] and others, corresponds exactly with that of pernicious anæmia.

If, however, the above-mentioned authors conclude from the results of the autopsies (atrophy of the mucous membrane of the stomach) that the disease of the stomach is the cause of the whole sickness, *i. e.*, of the anæmia—this, although it might be possible, is not as yet proven. For on one hand the proof is wanting that atrophy of the stomach can be found in all cases of pernicious anæmia, on the other hand not all cases of atrophy of the stomach show the symptoms of pernicious anæmia.

The atrophy of the stomach might perhaps be caused in these cases by the poor nutritive condition in consequence of the pernicious anæmia.

Ewald and Lewy later on gave exact microscopic pictures of the atrophied stomach. Ewald often found this condition in cancer of the stomach, and in people dying from "cachexia senilis."

In all these conditions not only the mucous membrane, but also the other parts of the stomach, were affected. In

* Read before the Society of German Physicians of New York.

† Derived from ὁ χυλός = the juice.

reference to this point, Meyer says: "In the affection in question the muscularis of the stomach is likewise affected to such a degree that the motion of the stomach is also disturbed. It is self-evident that in such a high degree of alteration in the mucous membrane of the stomach the resorbing faculty must cease. Thus the three functions of the stomach cease in consequence of the lack of parenchyma. This latter is signified in other organs as "phthisis;" therefore I do not see any reason why not to make use of the same name in these conditions of the stomach, as long as they are of a progressing nature. The condition, however, which the phthisis creates, namely, the total disappearance of the secreting parenchyma with its consequences, one could signify, according to Ewald, as "anadenia of the stomach."

As regards the symptomatology, Meyer says: "Should I summarize in a concise form the symptoms which in many instances make us diagnosticate phthisis ventriculi, there would be mainly the appearances of the progressive pernicious anæmia, with the only difference that the signs of the digestive tract take the foreground. . . . The duration of the affection seems to be from several months to about two to three years. In latter instances, digestion in the small intestines takes the place of stomach digestion; the duration, however, of this vicarious function of the small intestine is limited, and does not seem sufficient to maintain the nutrition of these patients for any length of time."

Thus, in most cases of atrophy of the stomach mentioned in literature the sickness in question is one in which all the functions of the stomach are disturbed, and which gradually leads to death; the name of phthisis ventriculi has, therefore, been very suitably chosen for the same. There have been described, however, a few cases of atrophy of the stomach in which the clinical symptoms or, more correctly, the chemical analysis of the stomach-contents led to the above diagnosis, which by no means seemed to present such a severe irreparable disease. In these cases no autopsies could be made, and atrophy of the stomach, although it must here be conjectured, is not as yet proven to exist. Cases belonging to this latter group have been described by Grundzach,[8] Ewald,[9] Wolff,[10] Jaworski,[11] Boas,[12] Rosenheim,[13] Litten,[14] and myself.[15] Grundzach especially urged the occurrence of this latter category. In his five cases the following conditions were noticed. "Stomach-contents: 1. When fasting always empty. 2. The contents always showed during the digestion neutral or very weak acid reaction. 3. There were found large amounts of mucus. Notwithstanding the lack of hydrochloric acid, there were no processes of fermentation going on."

Grundzach remarks that in patients of this kind prominent subjective symptoms may often be absent, notwithstanding the chemical condition of the stomach is disturbed to such a high degree.

"Whether such a condition can be of long duration, whether the muscular coat, put into the inflammatory state, does not after a while, under the influence of the disturbing factors, undergo changes which make it entirely incapable for the future of complying with its mechanical function, is a question that cannot be decisively answered."

As I had the opportunity to observe four pronounced cases of this so-called "atrophy of the stomach"—among which there is also the case reported in 1888, which I had under control for over four years—it appeared to me of value to publish these cases in order to discuss several points gained by them.

In reference to the name, it seems to me that in these cases, where until to date the diagnosis could be made only clinically, and there was as yet no opportunity for autopsies, the expression "atrophy of the stomach," "atrophy of the mucous membrane of the stomach," "phthisis ventriculi," or "anadenia ventriculi" is not fully justifiable. For in this name lies only the expression of the pathologic-anatomical condition of the stomach, which is not up to date known with surety. We feel obliged only by theoretical reasoning to accept this supposition.

As we have to deal in these cases with an entire lack of gastric juice, I believe that "achylia gastrica" might be a suitable expression for this disease. The name tells exactly what we find clinically in these patients. I may be allowed here to describe my cases in succession:

Case I.—Louis T—— (described in the New York *Medical Press*, September, 1888). This case deals with a man, twenty one years of age, who suffered since the year 1886 from obstinate constipation, vomiting, and headache.

The status, taken on November 26, 1887, was: Tongue heavily coated: the abdomen somewhat bloated. The internal organs do not seem to betray anything abnormal; the patellar reflex is present; no disturbances in the organs of sense; color of the lips and cheeks pale and anæmic, although the patient is by no means thin. His main complaint consisted at that time in vomiting after partaking of any kind of food, especially after meals. The examinations of the stomach contents undertaken in 1887, during three months always showed the absence of hydrochloric acid and of the pepsin and rennet-ferments. The diagnosis of atrophy of the mucous membrane of the stomach in all probability was made at that time. The treatment then undertaken had the effect of making the patient feel better and of causing the vomiting to appear less often than theretofore. (For details of the history of this patient see in the above-mentioned article.)

The condition of the patient has not changed much since then. The patient has gained, however, somewhat in weight; his face is now of a good hue; the color of the mucous membranes red. As a whole, patient could eat more than during the first two years of his sickness. The constipation still persisted in the old manner, and the patient had to make use all the time of clysmata and sometimes of purgatives. Headaches and a sensation of fulness and uneasiness in the gastric region are frequent complaints of the patient. About eight months ago a burning sensation appeared in the lower extremities; this symptom could not be stopped either by medicaments or by electrization; after a duration of half a year this burning sensation disappeared of itself. During the last two years the vomiting appeared only very seldom.

During the whole four years we have examined the stomach contents of the patient about once a month.

We always found the following conditions: When fasting, the stomach was usually empty, and only exceptionally contained a few cubic centimetres of a turbid gray greenish fluid of alkaline reaction and without the admixture of mucus.

One hour after Ewald's test-breakfast: The stomach contents can only with some difficulties be made to appear through the tube, because this latter becomes obstructed with the larger pieces of the roll. The stomach contents present, as a whole, the following condition: The pieces of roll appear almost entirely unchanged; they look as if they had been lying in water for some time; there is no mucus present; reaction very weakly acid (usually the acidity about 2 to 4); hydrochloric acid not present; lactic acid present in traces; propeptone as well as peptone not present; the rennet and pepsin ferments absent; stomach contents not decomposed. As a rule the above described condition was also found several hours after a test-dinner.

Case II.—August 15, 1890. Isaac S——, aged thirty-five, had suffered for ten years from vomiting, which appears sometimes immediately after a meal; usually, however, about two to three hours after. Sometimes the vomiting stopped for a week, in order to reappear regularly with renewed force. Appetite never present. Headaches, most severe in the morning. After meals there appeared constantly in the patient a feeling as if he would have to vomit, which feeling, however, subsided after a short time. Bowels regular. Bad taste in the mouth. Pa-

tient always felt weak, tired, and sleepy. Status præsens: Patient tall and looks pretty thin; cheeks of a pale hue; mucous membranes anæmic; chest organs intact; stomach not dilated.

August 16th.—One hour after the test-breakfast: HCl = 0; acidity = 6; rennet = 0; pepsin = 0; propeptone = 0; peptone = 0; achro-odextrin +; erythrodextrin = 0. The food particles quite large.

August 18th.—When fasting: 20 c.c. of a greenish mucous fluid; no admixture of food; reaction alkaline. Diagnosis: Achylia gastrica. Treatment: Lavage of the stomach; HCl; koumyss; powdered meat; gymnastics; cold ablutions. The patient feels much better; had no vomiting; appetite good; no headache.

August 20th.—When fasting: Stomach empty; lavage. Four eggs daily allowed in addition to the previous nourishment.

August 24th. — One hour after the test-breakfast: HCl = 0; acidity = 4; rennet = 0; peptone = 0; propeptone = 0; achro-odextrin + much; erythrodextrin = hardly traces; pepsin = 0.5 c.c. of the filtrate + 2 drops of muriatic acid + a disk of egg albumin, after six hours not digested; on the following day the disk is transparent, but still present. The filtrate contains many minute particles (probably from the egg albumin); the fluid even now does not contain any peptone nor propeptone. Pepsin therefore absent.

August 28th.—The so-called "Durchspritzgeräusch" (first swallowing sound) present. Patient is faradized for ten minutes from the inside of the stomach.

In October, 1891, patient asserts that he has gained four pounds during the last year. He has lived during the whole time according to the prescribed rules, felt well, and never vomited.

The examination of the stomach contents on November 10th, one hour after the test breakfast, shows: Reaction, weakly acid; HCl = 0; acidity = 4; propeptone, peptone, not present; rennet and pepsin absent; achro-odextrin + much; erythrodextrin absent; no admixture of mucus; the food-particles large; the pieces of roll look as if they were softened in water.

Case III.—October 1, 1891. Mrs. Caroline P——, aged fifty, had suffered for twenty years from stomach-complaints: first had stomach cramps, afterward vomiting also; usually the vomiting appeared periodically every three years; since a year, however, she used to vomit almost every day and had pains in the epigastric region. Appetite not good. Bowels somewhat constipated.

Status præsens: Well nourished, stately-looking woman; color of the lips and cheeks healthy; tongue not coated; chest organs intact; no splashing sound can be produced in the stomach. The epigastric region sensitive to pressure.

October 5th.—One hour after test-breakfast: The stomach contents can be obtained only with some difficulty, as the openings of the tube often become obstructed with pieces of roll. Reaction weakly acid; HCl = 0; acidity = 4; lactic acid can hardly be discovered; propeptone and peptone not present; rennet and pepsin absent; no mucus; achro-odextrin + much; erythrodextrin = 0.

Taking the long existence of the ailment into consideration, and the characteristic result of the stomach contents this case has been diagnosticated with all probability as one of "achylia gastrica," which diagnosis has been strengthened by the behavior of the patient.

The examinations of the stomach contents made thereafter for many months (about once or twice each month) always showed the same result; absence of hydrochloric acid; very low acidity; no peptone, no propeptone; neither rennet nor pepsin; no admixture of mucus; the pieces of roll absolutely unchanged.

The treatment consisted first in the use of HCl, condurango, and chloral hydrate until October 29th, but the vomiting had not disappeared. Since October 30th, direct faradization of the stomach once a week; since that time, no vomiting. Appetite, although not good yet, is better, however, than before.

As regards diet, the patient has been instructed to triturate the food as minutely as possible; she took koumyss, powdered meat, grated crackers and eggs beaten in bouillon.

During the last winter the pains of which the patient used to complain almost entirely disappeared, and she could eat more. The patient did neither gain nor lose in weight; the general condition, however, had improved to such a degree that the electrization could be dispensed with.

On April 10, 1892, the result of an examination of the stomach contents one hour after the test-breakfast was exactly the same as described above.

Case IV. *Achylia Gastrica, Combined with Rumination.*—August R——, fifty-two years of age, carpenter, was always well and had not consulted a physician for the last twenty years. Suffered in his boyhood from frequent headaches, cramps in the abdomen and diarrhœa until his twentieth year. The patient attributes the griping pains in his abdomen at that time to the circumstance of growing up under poor and miserable conditions; as a rule he had very little to eat; from time to time, however, he used to work in the country with the peasants, where he had plenty of good things to eat, and here the patient used to overload his stomach.

As a boy the patient partook of hardly any meat from his fifth to his fourteenth year of age; his main nourishment consisted of potatoes, flour, soup, bread, water—soup only occasionally; of meat he partook only when occasionally visiting his relatives. The patient did not like buttermilk nor coffee. When calling on his relatives, however, he used to drink a little coffee in order to enjoy the sugar which was given with it.

As long as patient can recollect he often used to bring up the food from the stomach into the mouth about half an hour after the meal, chew it and swallow it again. When eating cherries he used to swallow the pits also, and only afterward when bringing them up from the stomach into the mouth, he used to spit them out.

This bringing up of the food the patient used to do mainly when feeling well. In chewing the second time he enjoyed it as much as when first chewing the food. Often the food comes up in morsels, although the patient has not at all been thinking of it. The patient hardly ever vomited, except when he got drunk—which happened twice during his life—and when crossing the ocean on a trip to Germany, he vomited, but never at any other time. Patient eats hastily, and the hard substances he chews well afterward when they come up from the stomach.

The patient can ruminate any time he chooses, except when the stomach contains but very little or is almost empty. In ruminating the patient takes care to conceal this act from others; he speaks to no one about it, and even his wife is not aware of his ruminating.

Status præsens: Strongly built man of short stature, is well fed, with good panniculus adiposus; chest organs intact; stomach dilated; the lower margin extending to one finger-width above the navel. Patient has no complaints whatever, enjoys a good appetite, his bowels are regular, and he feels well in every respect. The only thing which strikes him as being abnormal, and wherefore he has been treated for some time in Germany and afterward came to see me, is his coated tongue.

October 27th.—One hour after the test-breakfast: Patient spontaneously brings up a small quantity of the contents of his stomach (about 20 c.c.). With the tube, likewise, only a small quantity can be obtained. The roll particles are not minutely minced and almost unchanged. HCl = 0; acidity = 2; rennet = 0; propeptone = 0; peptone = 0; erythrodextrin = 0.

Meltzer's swallowing sounds: Patient drinks water; at the first swallow one hears simultaneously a sound at the

processus xyphoides ("Durchspritzgeräusch"); at the second swallow (which followed about one to two minutes later) one hears a sound about eight seconds afterward ("Durchpressgeräusch"); at the third swallow one immediately hears the "Durchspritzgeräusch," and ten seconds later the "Durchpressgeräusch."

I had the opportunity of examining the patient for three months, and always found the stomach contents in the above described condition, with the same result of chemical analysis.

This last case is in many ways very interesting. At first we can learn, that the "achylia gastrica" may be found in a person not aware of any troubles from the digestive apparatus, and enjoying perfect health.

The history of the patient seems to indicate that the abnormal condition of the stomach developed in his early youth; for only at that time the patient had complaints, whereas later on he had no disease whatever. This would clearly show that the achylia gastrica may exist forty years without endangering the vital functions of the organism.

As to the etiology, it is of importance that the patient in his early boyhood did not partake of any meat nor of any other richly albuminous food. As the infantile stomach secretes a juice which does not contain much hydrochloric acid (see my article[16] in the *New York Medical Journal*. "The Time Required for the Stomach Digestion of Different Foods in Infancy"), it might be imaginable that in our patient this faculty of the stomach of secreting an acid juice did not further develop. For the acid juice in the stomach of this patient, who lived on a scanty diet consisting mainly of vegetables, where there were almost exclusively amylaceous substances, would be not only of no use, but rather of some detriment to digestion. (As is well known, the conversion of starch into sugar is interfered with in the presence of a considerable amount of acid.) In this way the stomach might have secreted during the first years of boyhood only a scanty amount of hydrochloric acid, and may later on, under the influence of other disturbing factors (frequent acute gastric catarrhs, etc.), have lost entirely its secreting faculty.

The rumination could be explained from the etiological standpoint by the early appearance of the gastric achylia or lack of juice. For in the achylia the vegetable food particles remain in the stomach unchanged, as the enclosing plant-albumin does not become dissolved (this fact was first shown by Reichmann[17]). The starchy grains, the coverings of which have not been opened mechanically in the mouth, escape in this way the conversion into sugar. Thus the trituration of the food into very fine small particles forms the best means of ameliorating this disadvantage.

The rumination in this case may perhaps have been developed for teleological reasons. For by the rumination the patient is enabled to divide the food into very fine particles in chewing it a second time.

In shortly again perusing the cases of achylia gastrica mentioned, we find — if we exclude the fourth last described case in which there were no troubles whatever — that these patients complained of frequent vomiting, loss of appetite, and of a sensation of fulness or pains in the epigastric and gastric region.

The appearance of the patients was good, *i.e.*, they were well nourished and did not look in any way thin or sick, with the exception of Case II., who was somewhat emaciated, but did not lose in bodily weight since the treatment.

In the fasting condition the stomach contained in Cases I. and II., during the first time of treatment, a small amount of turbid fluid with an alkaline reaction, in which were found decayed epithelial cells; after a short time of treatment the stomach was empty. In the other two cases the stomach was empty when fasting.

In all the four cases the stomach-contents showed, one to one and a half hour after Ewald's test-breakfast, the following peculiarities: 1. The pieces of roll not minutely minced and unchanged. 2. The reaction very weakly acid or neutral, usually the acidity was 4 (*i.e.*, 100 c.c. of the filtrate of the stomach contents are saturated by 4 c.c. of a $\frac{1}{10}$ standard solution of sodium hydrate). 3. Hydrochloric acid not present. 4. Lactic acid present, but could be discovered only after a thorough shaking with ether. 5. Neither propeptone nor peptone present. 6. The tests for the pepsin and rennet* ferments gave negative results. 7. The stomach contents did not smell badly, and did not otherwise give the appearance of decomposition.

The clinical points above mentioned in connection with the result of the examination of the stomach make the diagnosis of "achylia gastrica" quite easy.

In treatment we must lay most stress upon a minute mechanical trituration of the food before partaking of same, for the stomach itself, in want of its faculty of dissolving albumin, as mentioned above, is not able to open the coverings enclosing the starchy granules.

The tonic remedies of the stomach, as, for instance, lavage and direct faradization, appear to be very useful. HCl was of advantage only in one of the cases; in the others it seemed to have no influence whatever. Pancreatin, which has been recommended by Reichmann,[17] Ewald,[18] and Boas,[19] I have given only in one of the cases without decided effect. As regards the course of the disease after the above-described treatment, it seems to me that the regulation of the diet proves to be very useful and of great advantage. In the three cases in which there were symptoms, it succeeded in stopping the vomiting and in decreasing the other complaints of the patients.

In all cases of absence of gastric juice the act of digestion is executed principally by the small intestines. I do not say exclusively, because the conversion of starch into sugar, as long as the starch granules are free, begins in the mouth and proceeds, and is nearly completed, especially in these cases, in the stomach. All albumin must, however, wait for its digestion until its arrival in the small intestine. If the food particles are very minute, the vicarious action of the small intestine comes into play much easier, and the subsistence of the organism can in this way proceed without injury. If the stomach forwards its contents in due time into the small intestine, and if the latter is enabled to do the increased work perfectly, then there exists a state of compensation, and the organism is again in its equilibrium. In this case the patients can live many years even without any complaints.

Should we be entitled to draw some conclusions from Case IV., it would seem as if the compensation can be achieved more easily and perfectly during early youth. For, whereas all three other cases must live according to the prescribed diet, in order to maintain the balance, this is not the case with Patient IV. He eats anything, and it agrees with him. The rumination alone would hardly have effected this remarkable difference; but the rumination, combined with the early adaptation of the small intestine to replace the functions of the stomach, has enabled the patient to digest perfectly.

According to this explanation, those affected with achylia gastrica, after established compensation, can exist for an unlimited length of time (Case IV. is probably in this state since his early youth, therefore about forty years. Patient Louis T—— did not get worse during the four years after treatment was undertaken). I would like to lay special stress upon this point, as there is nothing certain about it in the literature.

As the pathologic-anatomical base we might with some certainty suppose in all cases of gastric achylia a complete atrophy of the mucous membrane of the stomach; however, this has not as yet been actually proven.

The etiology of achylia gastrica is likewise not yet positively known. It is supposed that grave catarrhal con-

* The rennet zymogen, however, may still be found present.

ditions of the stomach lead to atrophy, and in this way also to achylia. For this reason Jaworski and Boas have designated that form of the gastric catarrh which is accompanied by a high diminution of the secretion of hydrochloric acid, and which goes on without formation of mucus, as the atrophic form, "Catarrhus chron. atrophicans." I, myself, had the opportunity of observing several cases of gastric disturbances, where cancer could be positively excluded, with a constant absence of free hydrochloric acid, but with the presence of the pepsin and rennet-ferments. Besides, I have known a young lady with no complaints whatever, and a flourishing and healthy appearance, to present the same condition of the stomach. These cases I have fully described in my article,[20] "Therapeutic Results of Direct Electrization of the Stomach." Should we observe in these cases with a lack of hydrochloric acid that with time the ferments also disappear, then the development of the achylia gastrica out of the grave forms of the gastric catarrh would be proven. Thus far such observations do not as yet exist, and it would be desirable to pay special attention to these points in the future.

COMPRESSION—THE CURE FOR SWOLLEN BREAST AND FOR SWOLLEN TESTICLE—TWO NEW APPLIANCES.[1]

BY TALBOT R. CHAMBERS, M.D.,

EAST ORANGE, N. J.

THE old treatment of rubbing caked breast has not unfrequently been the direct cause of abscess, and is irrational. Take as a rough illustration a bunch of grapes and snugly pack it in a close-fitting bag. Rub the surface of the bag like the human breast was formerly done and consider the result. The grapes are bruised and their jackets burst. The rough handling of the human breast at any time, especially when in an inflamed state, may be followed by abscess or possibly by the initial steps of cancer.

The custom to day is to apply a strip of muslin or other material around the chest which shall compress the caked breast and cause resolution of the induration, no matter what the cause unless it be tumor growth. In Orange Memorial Hospital a double strip is employed, one portion going above and one below the nipple line. It was first used in the Boston hospitals. It has its disadvantages. It requires skill and experience in its application and then is often painful, cumbersome, and dirty.

In order that a muslin bandage may be effective it must be put on tight. It is then unyielding and the patient feels as if in a vice. While annihilating the disease, it almost annihilates the patient. I do not claim that the muslin binder is always clumsily applied, but there is no doubt the majority of those applied are unnecessarily painful and awkward and not a few, perhaps, have done harm rather than good.

The principle is right. I can testify that during the past six years in no case where the bandage was properly applied, have I seen an abscess of the breast. During my eight years of practice previous, I had the misfortune to see one or more every year. The experience of the members of this Society has been similar.

To gently stroke the breast at or immediately about the nipple where the milk-tubes are straight, is rational and effective and does no harm. For the rest of the gland, if induration occur, compression—gentle, gradual, constant, firm compression alone should be used, and used early before suppuration has taken place. Gently but firmly oppose the centrifugal tension of the mammary body, whether the swelling be due to accumulation of milk, or to mastitis, or be from traumatism. Perhaps most cases of cancer of the breast have their causation in an injury of the breast. There may have been laceration of tissue with extravasation of blood or only a slight bruising with a limited exudation. This induration was benign in character and should have been resolved, but instead, acting as a foreign body, after a while it changed to malignant in character. Compression in the early stage here might have saved suffering and prolonged life.

All inflammations tend to recovery. They recover by resolution or suppuration. Unaided, permanent damage often results.

Now, convinced of the propriety of early compression for indurated breast, and disgusted with the working of the plain muslin bandage, I have experimented during the past year with what I have termed the "Caked Breast Cure," as a result.

It is an appliance to carry out the principle of equable, comfortable, cleanly, effective compression. Its rubber shields are accurately fitted by the dressmaker's art to the female form. It may be readily tightened or loosened by means of the corset-lacing behind and the shoulder-straps in front. The hand gently passed beneath, the shield lifts the breast into a comfortable position with the nipple escaping through the nipple-hole in the shield. It does not interfere with respiration. Without any previous experience in its use, the patient will readily understand it and its application. The milk runs over the outside of, and cannot get beneath, the shield. It is to be worn constantly, day and night, just as your muslin bandage.

The rubber has a peculiar charm of its own, acting kindly upon the irritated or inflamed breast beneath. It is only worn for a limited time, until resolution has taken place. The perspiration induced in some cases proves an advantage rather than a drawback. It may be washed. It is light and cool. It is scarcely possible for this appliance to do harm and the ease with which it is understood makes it peculiarly helpful to the obstetrician.

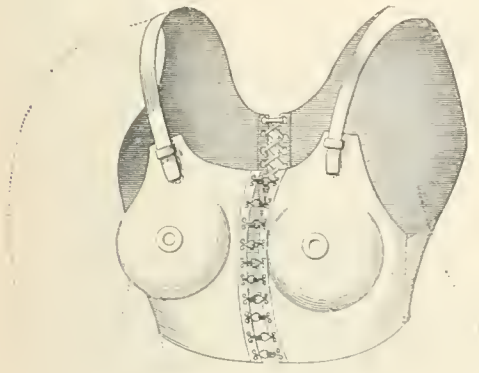
The only criticism that I have heard against it, is that it tends to dry up the milk. Well, so does the muslin bandage Care must be taken not to keep it on till so unfortunate an event should happen. I know that it has been a great comfort to several cases in which it has been employed for that purpose. Belladonna plasters were employed in addition and the desired result took several days, during which time the pressure might have been relieved before the milk had dried up completely.

I have shown the appliance to a number of my professional brethren in the Oranges and Newark and without exception they agree it will prove a help to the attending physician and a comfort and speedy relief to the sufferer with swollen breasts. All the nurses and patients who have seen or used it are enthusiastic in regard to it. It is not recommended when pus has formed. Then the poultice and knife and possibly this appliance afterward,

[1] Read before the Orange Mountain Medical Society and the Practitioners' Club, Newark, N. J.

to keep the abscess-walls in contact, would be the order of things.

The Caked Breast Cure is manufactured by the C. B. C. Co., P. O. Box 61, East Orange, N. J. It is made in two sizes, the smaller being for chests from twenty-six to thirty-one inches, and the larger size for those over thirty one inches.



With the idea in mind that compression of the inflamed mammary gland in its earlier stages is pain-relieving and curative, as certified to by the profession at large, I have sought to find out if, after all, the same principle might not apply to the inflamed testicle, a gland of very similar anatomical construction.

Compression in the early stages of swelled testicle was tried many years ago, but abandoned because no appliance was found which would fill the bill. I believe the difficulty has been overcome in the automatic appliance introduced in this paper.

Without going into the anatomy of the testicle, please call to mind the tunica vaginalis, albuginea, and vasculosa; the lobules and tubules, both straight and convoluted, with the lymph and blood-vessels and nerves, and you will see that blood-vessels freely supplied with sensory nerves make up a considerable part of the parenchyma of the gland; secondly, that the testicles hang freely in the scrotum, following every motion of the pelvis to which they are attached, and thirdly, the numerous convolutions of the tubes present a marked general resemblance in structure to the mammary gland.

In inflammation the first stage is congestion. There is an increase of the quantity of blood at the zone of inflammation. This of itself causes a swelling of the part, with increased pressure (whose degree corresponds with the elasticity of the enveloping tissues) there must necessarily be and is an exudation of serum and lymph, and blood if the inflammation is very violent. The cells of an inflamed gland are swollen, either from the increased nutrition or from the presence of the serum or from the peculiar action of the poison causing the inflammation. If the distention be rapid, the circulation in the capillaries is arrested by the pressure. If the capillaries are stopped there can be no arterial nor venous circulation and there is stagnation and death of the part. As Bryant says, death of a part is not due to cutting off the blood-supply to the inflamed part. The blood is in the tissues, but it does not circulate. It is from the stasis of its own blood-supply. He calls it static not dynamic gangrene.

In orchitis there are congestion of the fibrous stroma, swollen cells and exudation, all within inelastic walls. The pressure is centrifugal and relief is obtained by the way of least resistance, beneath the tunica albuginea, along the cord, hence the œdema of that part.

If effusion be excessive, death of parts may occur without inflammation.

Bryant in "Wood's Medical and Surgical Monographs" aptly states: Pain has always a common relation to tension. In parts poorly supplied with sensitive nerves there may be tension and no pain, as in an ovarian cyst. The distention of the mammary gland with its normal secretion is often most painful even without inflammation. The sprained joint becomes painful according to the degree of the swelling and tension.

By far the most common cause of swelled testicle is gonorrhœa, which makes the reason plausible why epididymitis is more frequent than orchitis. It would seem the inflammation passes by continuity from the urethra or prostate along the vas deferens and the explosion expends itself on the epididymis before reaching the testis. Gonococcus has not as yet been reported in the effusion of swelled testicle. With traumatism, mumps, gout, or syphilis as the exciting cause, the testis is involved. According to Ashhurst's "Surgery," the two always coexist, the one or the other being the more prominent.

Now, whatever the cause is, a sprained ankle, caked and swollen breast, distention of the eye by glaucoma, or swelled testicle, the thing to do is to diminish the blood-effusion and tension in the part, especially in the early stage before inflammation has been thoroughly developed and before suppuration has taken place. By so doing you save pain and abort the disease. For the sprained ankle you use hot water to accelerate the circulation and prevent stagnation and follow with compression by the Martin rubber bandage. For the glaucoma, early iridectomy, relieving the pressure, has saved many an eye.

Bryant says: Tension has a marked effect upon the progress of disease. It stands foremost among the causes of pain and in inflammation it is probably the chief factor. Tension in every degree has a destructive tendency and the rapidity of the destruction has a direct relation to the acuteness of the tension.

It is for these reasons that I hold, the sooner the tension is combated in swelled testicle the better it is for the patient, even though the cure might be painful, which it is not, if properly managed.

It is better to wait in mastoid disease until suppuration has destroyed all the bone-cells than to open early. Surely, then, interfere in the inception of swelled testicle. Do you wait for fluctuation in the caked breast before applying your compression? No indeed. Many a breast bandage is worn to day when the nursling is only three or four days old.

Call to mind, some very severe case of swelled testicle you have had under your charge. Did it not take several days before you could ameliorate the terrible sickening agony? Perhaps tartar emetic, the tobacco poultice, the meal poultice, ice-bags, hot-water bags, the ointments of iodoform, iodol, or carbolic acid, or possibly leeches were used. Perhaps Keyes's treatment of puncturing the testis was employed. Were you satisfied with any or all of these treatments? I can honestly say that I have not been nor has the patient. Hasn't the cure been worse than the disease? The patient has suffered the treatment because, like the old lady who was resigned when she died, she had to be. The patient was compelled to remain on his back with some support for the heavy, tense and swollen organ. The calls of nature were only with difficulty answered. The patient was a very sick patient. He had more or less fever. Morphine in large quantities was necessary perhaps. A nurse was necessary. In the later days strapping was employed on the diseased organ. This manœuvre of strapping is certainly a subterfuge for something better to do. You must shave the scrotum and to carry out its purpose reapply it daily. I hold that strapping is simply barbarous when other so much more satisfactory means are at hand.

Andrews suggested a piece of rubber sheeting be drawn snugly around the swollen testicle and held by a strip of adhesive plaster. This needs more or less readjustment and is inconvenient.

Another plan has been suggested and is in use to day. A thin rubber air-bag, large enough to cover perhaps one half of the swollen testicle, is applied in the collapsed

state against one side of the testicle. The surgeon wraps a piece of cotton or linen around the whole and ties or straps it into a constriction above the swelling. The tube of the air-bag is allowed to escape through a hole in the linen. The bag may then be inflated at will.

Dr. Hawes of California, has a double walled rubber envelope by which he makes compression on a similar plan.

Somebody has proposed two hollow egg-shells of hard rubber perforated with holes through which strings pass and which when tied compress the testicle.

In New York in one clinic the dry poultice is used, in another the scrotum is lightly touched several times with the actual cautery and iodoform dressing is then put on covered with oiled silk or rubber tissue.

In swelled testicle we have an increased quantity of blood with the effusion of lymph in and about the organs in the scrotum and great centrifugal tension. If these two enemies may be repulsed the disease is aborted. If an appliance could be comfortably placed very tightly around the neck of the scrotum, it will by its constriction diminish the arterial supply which is already to a slight degree impeded. And if at the same time compression may be firmly brought to bear all over the scrotum and its contents a little more than is necessary to prevent the venous congestion consequent on the constriction around the neck of the scrotum, the purpose is accomplished. Then if the freely movable diseased and supersensitive organ shall be firmly held against the pelvis and all motion of it stopped, we have all the indications met.

It is with pleasure I offer an automatic appliance which escapes many of the criticisms of the appliances alluded to and so far excels the tobacco or other poultice that, once you have seen its kindly effective action, I am sure you will agree it is the best means of cure for swelled testicles to-day.

The appliance has received several improvements since it was first given out and is now nearly perfect.

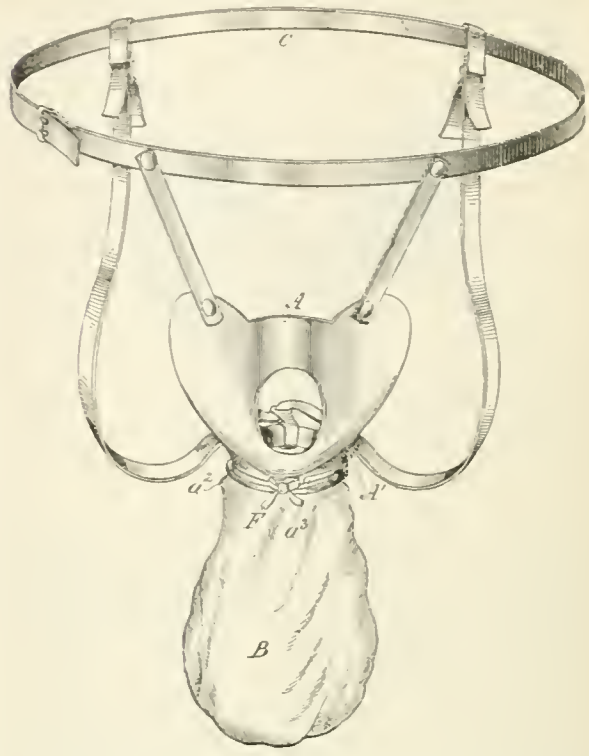
I can record a number of cases where the relief of pain was marvellous. The principle in this case is right, as it always was. The appliances have been faulty. In this appliance the pressure is automatic. It is steady, constant, firm, equable. It is not unyielding nor are there any sharp nor hard surfaces. Both, not the diseased testicle only, are included in the compress. It has been found that the innocent testicle is not made to suffer with the wicked organ but is made to share its joy at the relief from pain which comes as soon as the appliance is properly put on.

In ordinary practice some cases avoid going to bed who should. And some go to bed who, with proper attention, might be saved much loss of time, pain, and annoyance.

With the compressor properly placed none need go to bed. It is coaxing, not brute force, compression. It yields a little at first, but its ever-persisting action quietly limits the attack and hastens the organ back to its natural size, thus aborting the disease. Pain, fever, and malaise are all relieved. The patient need not go to bed with the pillow or other support, nor need he suffer at every call of nature. He may attend to ordinary business duties without loss of time. The appliance is not cumbersome and the disease not so awkward as by the old treatment. The compressor is readily adjustable, comfortable, neat, clean, compact and does the work. There is no need for greasy applications nor strapping. The patient's most intimate friends may remain in ignorance of his unfortunate infirmity.

The compressor consists of three pieces: An army and navy suspensory bandage made of elastic tapes; a gutta-percha shield which is supported above by the suspensory and which has a channelled collar to clasp the neck of the scrotum (this collar may be fastened as tight as desired by tying the tapes in front); the chief factor of the appliance is the rubber bag compressor. Two go with each appliance. The light one is put on first and facilitates the drawing on of the heavier or real compressor.

This compressor bag is cured after being blown up. The curing process is only carried to a certain degree,



the interior between the two surfaces being raw rubber. Now when exposed to the heat of the body, the bag tends to contract to the size from which it was originally blown, Herein consists its automatic action.

This bag is large enough that when stretched it will and may be made to include and cover both of the closed fists. They are sold by L. M. Weed & Co., surgical instrument maker, East Orange, N. J.

Nitric Acid and Criminal Abortion.—Dr. Bellin, of Charkoff, read, last fall, before a medical society in that city, a remarkable paper on eight cases of nitric acid drinking to produce abortion. The subjects took at first from fifteen to twenty drops of the acid several times a day, gradually increasing the dose. Severe symptoms appeared at the end of a month or six weeks. Abdominal pains, nausea, vomiting, constipation, and subnormal temperature were observed, with remarkable mental symptoms. The patients also grew thin. In the first case abortion took place at the third month and the patient was cured. In the second, abortion occurred at the same stage; the patient suffered miserably from abdominal pains afterward and ultimately killed herself. The third patient became insane. The fourth aborted at the fourth month and recovered. The fifth did not abort and recovered. The sixth committed suicide by swallowing matches, owing to the intense pain from which she suffered. Abortion occurred on the day before death. The seventh patient took the acid for two months without abortion occurring; she was syphilitic. The eighth, also subject to syphilis, took nitric acid for five weeks during the second and third months of pregnancy. She was delivered of a macerated fœtus at the sixth month and became insane. In all these cases where abortion occurred it happened when the poisonous effects of the acid were most marked, or later after they had been counteracted. Bellin believes that the pathological changes caused by nitric acid depend upon the influence of that acid on the composition of the blood.—*British Medical Journal, supplement.*

New York, June 11, 1892.

THE AMERICAN MEDICAL ASSOCIATION MEETING.

THE Detroit meeting of the American Medical Association, a full telegraphic report of which appears in this issue, may be regarded as one of more than usual importance from the point of view of attendance, as well as of the quantity and quality of the scientific work presented. The Sections were much better attended than at some of the previous meetings, and the interest taken in their work was such as to encourage the friends of the society to persevere in their efforts to rouse it from the apathetic state into which it seemed to be falling, and to infuse new life and energy into its scientific discussions.

That the old political schism, which was formerly so strong in the Association, is not wholly dead, was demonstrated very fully during the General Session on Wednesday. The action of the Judicial Council in withdrawing the privilege of membership from Dr. Potter must be regarded as unwise and illiberal, whatever may be said concerning its legality and justice. It precipitated a very heated discussion, which at one time threatened to degenerate into a disorderly row, a disaster which was only avoided by the able management of the President. Although it was asserted that the decision of the Council was final, yet its action was really reversed by a resolution introduced by Dr. Gihon, which provided that, until the special committee had reported upon the status of Drs. Potter, Van Derveer, and other permanent members from New York State, their registration and signature to the certificate presented to them should be considered *prima-facie* evidence of their standing and qualification for all the rights and privileges of permanent members.

In contrast to this action of the Judicial Council was the adoption of a resolution calling for the appointment of a committee to revise the Code of Ethics of the Association. This resolution had also been foreshadowed in the President's Address, a document which was characterized by broadness and liberality in its discussion of the delicate Code question.

The social part of this Convention, while rightly kept subordinate to the scientific, was not the least enjoyable feature of the meeting On Tuesday evening a reception was tendered the members of the Association and their ladies, by the medical profession of Detroit; on Wednesday evening the delegates were received by Mayor Pingree, General R. A. Alger, Mr. George S. Davis, and Mr. Frederick K. Stearns; and on Thursday there was an excursion on the Detroit River and Lake St. Clair. The weather was abominable, but that was nobody's fault, and served only to accentuate by contrast the kindly hospitality of the profession and citizens of Detroit.

Finally, we may add that the selection of Milwaukee, instead of Chicago, as the place of meeting for the Columbian year seems to us most wise, for the latter city, however enjoyable and instructive a visit there may be, will be no place for the holding of scientific conventions in the year 1893.

LA FEMME NERVEUSE.

So many varied conditions go to make up that mysterious entity, the nervous woman, that we are somewhat surprised at Deschamp's temerity in attempting to study her from a psychological and psycho-therapeutic stand-point (*Bulletin Gén de Thérapeutique*, February 15, 1892). There are plenty of neuropaths among the men, and it is highly probable that there would be quite as many nervous men as nervous women if every man possessed a uterus and a pair of ovaries. The essayist does not take this view of the question, however, but thinks woman is the being in whom, by heredity and culture, the nervous system has taken on the more intense development. For him the "nervous" are those who, endowed with an exaggerated sensibility, have not sufficient reasoning power to direct their volition. He divides them into three principal classes: The cerebral, the genital or sensual, and the neuropathic. In the first class we find a type of the superior sort of woman, who combines with finesse tact and delicacy, frankness, high-mindedness, disinterestedness, and a taste for manly occupations; for she is intelligent and directed in her acts by the things of intelligence.

Voluptuous preoccupation characterizes the sensual. She is clever, bright, but indelicate. She is cunning, but a cheat, and given to dissembling and prevarication. If circumstances warrant it, she loses all reserve, all check, and all sense of shame. The gifts of honesty and straightforwardness which her cerebral sister enjoys are here not to be discovered.

The simple neuropath is not so interesting a creature. She is the plebeian of nervous womankind. If of sensitive nature, she is ready to be ruffled by any passing trifle, and foolishly moved by every little thing If of the motor variety, she is never quiet or at rest, makes much ado about such nothings as directing her household affairs, and gives herself the airs of a hero taking a city by storm. She is convinced that nothing would go right without her superintendence, and in many other ways is quite as disagreeable as the sensitive neuropath.

The treatment of this condition is one of prevention. It is in the infant that we must study the woman of the future, and by physical and moral education strive to cultivate the *volonté* and combat the *caprice*.

Instruction should have for its aim the development and formation of the intelligence; there should be a broadening of the mind, so that the young girl can learn to reason and understand the ridicule which her caprices will bring upon her. The various ways of influencing the youthful mind to this end, as set down by the writer, are worthy of consideration, and if their application will result in a generation of strong-nerved women, it will be

much more practical than any subsequent attempt to cure by hypnotism, drug medication, or injections of nerve matter.

BRAIN ABSCESS FROM EAR DISEASE.

An elaborate memoir by Körner (*Archiv für Ophthalmologie*) and an admirable critical review by Le Fort and Lehmann (*Gazette des Hôpitaux*, March 26, 1892) bring together the facts at present known regarding the subject of ear disease and brain abscesses. Inflammation of the ear is credited with causing one third to one-half of all the abscesses of the brain. Since the time of aseptic surgery there is no doubt that the ear plays, relatively, a greater part in causing the brain disease. Chronic otitis media is usually the starting-point, it being only in rare cases that an acute process is the cause, and when the labyrinth, external ear, or mastoid is involved, it is usually secondary.

Brain abscess from ear disease occurs two or three times oftener in the cerebrum than the cerebellum, the latter ratio being more correct. If in the cerebrum, it is the temporal lobe that is almost always involved.

Various views have been expressed as to the seat of the abscess and its relation to the seat of the ear disease. According to Körner, lesions of the tympanum and mastoid cells cause brain abscesses, lesions of the labyrinth, and cerebellar abscesses. Others have stated that mastoid disease is more liable to cause cerebellar abscess. Robin asserts, on rather insufficient data, that sinus thrombosis and cerebellar abscess occur oftener in adults than in children. Probably, as Pitt suggests, much depends on the individual variations in the shape of the skull and the course of the sinuses.

There is no question at present that the abscess is caused by microbic infection along the venous and lymphatic channels. In recent times the existence of meningitis and phlebitis has been oftener recognized than formerly. Brain abscess from ear disease occurs more frequently on the right side than the left; it is rarely seen after forty years of age, and is found more frequently in persons under the age of ten (Körner). The abscesses are single in about five-sixths of the cases, and they are accompanied with meningitis or phlebitis in three times out of four. In the cerebellum they are always in a lateral lobe, the pus has often a fetid odor.

The symptoms are best classified under the head of those of suppuration, those of pressure, and those of local irritation or destruction. Much has been said about the temperature, and about all that can be gathered from various experiences is that the fever curve is very irregular, that there is often a normal or subnormal temperature; chills are certainly rare. Headache—often intense—vomiting, slow pulse, falling to 40 or 50, irregular respiration, mental hebetude, are acknowledged to furnish valuable indications. Optic neuritis sometimes exists, but not very often. Little can be learned from the state of the pupils. Dryness of the tongue, constipation, nausea, local tenderness and hyperthermia, aphasia, hemiplegia, emaciation, strabismus diplopia, are all minor signs which may have some importance. While there is no pathognomonic sign of this disease, the history and course generally make its recognition easy.

The treatment is necessarily surgical. A great many methods of operating have been devised, but probably the rule suggested by Barker, and modified by Stoker, is the best. A line is drawn 1¼ inch back from the external meatus, and from the end of this a vertical line is erected 1¾ inch in length. The trephine is applied at this point if a temporal lobe abscess is suspected. If there is phlebitis, the jugular vein and lateral sinus are opened and washed out. The successes so far, in forty-four cases, have been fifty per cent.

THE NEW QUACKERY.

No one who has read the daily papers for the last decade or two can fail to notice the curious change which has occurred in the methods of advertising adopted by the quacks who patronize their pages. It used to be the custom to advertise the specific power of certain pills or mixtures, accidentally discovered perhaps by some unselfish clergyman while teaching the natives of Central Africa or South America. The reader was assured with positiveness of the unvarying efficacy of the cancer-cure, consumption-cure, and kidney-cure in question.

Now, however, the tendency is for quacks to publish short clinical lectures and reports of cases, with pictures of some grotesquely healthy individual who had suffered martyrdom from Bright's disease or catarrh before he happily fell into the hands of the celebrated Dr. X. The quack often portrays with some fidelity the ordinary symptoms of the disease he especially treats. In this way other sufferers recognize and get a name for their ailments, and their minds are turned hopefully toward the confident advertiser. Then the record of cure is made complete by a letter from the patient, and what further evidence can be asked?

The modern quack is less of a fool and an ignoramus than his predecessor. He is sometimes a man of good medical education and experience; and has, perhaps, learned the methods of treating catarrh, fits, phthisis, Bright's disease, rheumatism, and neurasthenia, ordinarily employed by physicians. His essential distinction is that he advertises dishonestly and practises dishonestly, for he promises what he cannot surely do. Perhaps on the whole he does not do quite so much harm as of old. As to whether he thrives as well we cannot say; but it seems improbable. The modern quack has to hire a whole column of a newspaper, and perhaps occasionally a hall, in order to beat his rivals; and every year it looks as if, to be successful, he must advertise more. Eventually the time will come when it will cost so much to advertise successfully that the quack will be driven, perforce, to honest methods. The development of the modern quack is a good argument, if any were needed, against the advice that doctors ought to advertise like other people who seek business patronage. Aside from any question of morality and propriety it would soon be found that the practice would become an economical impossibility.

A single child, sent to school before complete recovery from scarlet fever in one of the arrondissements of Paris, was clearly shown to have been the direct cause of a hundred and fifty other cases of that disease with eighteen deaths.

News of the Week.

The Twenty-fourth Annual Commencement of the Woman's Medical College of the New York Infirmary was held on May 27th, and a class of twenty-one was graduated.

A New Medical Senator in France.—M. Labbé, the well-known Paris surgeon, has just been elected Republican senator of the Department of Orne.

Dr. Charles Buchanan, F.R.S., has been knighted on retiring from the post of Medical Officer to the Local Government Board. Dr. Buchanan is a distinguished sanitary worker. One of his best-known reports was that in which he showed a relation to exist between the distribution of phthisis and dampness of soil. His researches on this subject were in point of time anticipated by those of Dr. Bowditch, of Boston, but Dr. Buchanan's work was independent and carried on in ignorance of what Dr. Bowditch had done.

Arizona Medical Association.—The first medical society ever organized in Arizona was formed at Phœnix, on May 25, 1892. A strong and rigid constitution was adopted, and officers elected as follows: *President*, Dr. J. Miller, of Phœnix; *Vice-Presidents*, Dr. A. Martin, Phœnix; Dr. M. M. Gilbert, Mesa City; Dr. I. B. Hamilton, Tombstone; *Secretary*, Dr. John Traill Green, Tucson; *Treasurer*, Dr. W. H. Sullivan, Tombstone.

American Association of Andrology and Syphilology.—The sixth annual meeting will be held at the Spring House, Richfield Springs, N. Y., June 21 and 22, 1892.

The Medical Society of New Jersey.—The next annual meeting of the Medical Society of New Jersey will be held in the United States Hotel, Atlantic City, on Tuesday and Wednesday, June 28 and 29, 1892.

The American Climatological Association meets at Richfield Springs, N. Y., June 23d and 24th.

Dr. M. C. O'Brien, formerly House Physician to Hospital for Nervous Diseases and Epileptics, and Charity Hospital, has been appointed Neurologist to the Harlem Hospital Dispensary, by the Commissioners of the Department of Public Charities and Correction.

American Neurological Association.—Eighteenth annual meeting will be held at the New York Academy of Medicine, June 22, 23, and 24, 1892.

The Medical Society of the State of New York.—The Business Committee of this Society has been organized for the meeting of February, 1893, by the appointment of Dr. Seneca D. Powell, of No. 12 West Fortieth Street, New York City, Chairman, and Drs. William Maddren, of Brooklyn, and John O. Roe, of Rochester, Associates. The programme for the scientific work of the session is already well advanced in its preparation.

Ralph Cross Huse, M.D., died of Bright's disease at Georgetown, Mass., June 1, 1892. He was born at Newburyport, Mass., August 21, 1843. He graduated at Harvard Medical School in 1856. He was appointed acting Assistant Surgeon United States Army, on November 7, 1864, Third New York Volunteers. He served in the army of the James, North Carolina; siege of Fort Fisher, where he was wounded in the thigh; also private, Co. A, Forty-eighth Massachusetts Volunteers, with General N. P. Banks, 1862–63; Baton Rouge and Donelson. His services terminated May 31, 1865, by reason of the wound received at Fort Fisher.

Dr. William R. Birdsall, of this city, died June 7th. He was graduated from the University of Michigan in 1876 and the College of Physicians and Surgeons of New York in 1877. He was Attending Physician at the Manhattan Eye and Ear Hospital and the Deaf and Dumb Asylum, and an active member of the County Medical Society, the Academy of Medicine, and the Lenox Society. He was forty years of age and leaves a widow.

The Medical Association of the District of Columbia, we learn from the Washington newspapers, has incorporated in its by-laws the following declaration: "No graduate of medicine shall be eligible to membership in the association who shall not devote his entire time to the practice of medicine." This is aimed at the department clerks who have obtained a medical degree and practise after office hours.

In Memory of Professor T. G. Richardson, M.D.—The following resolutions have been unanimously adopted by the faculty of Tulane University of Louisiana:

Whereas, Professor T. G. Richardson, M.D., was called to New Orleans as a citizen by the Medical Department of the Tulane University of Louisiana, and continued his connection therewith from April 19, 1858, until severed by death, May 26, 1892, and having given to the Medical Department thirty-one years of active service, fourteen years as Professor of Anatomy, seventeen years as Professor of Surgery, and twenty of these years as Dean; and having also given during the last three years of retirement from active service the most convincing proofs of his great devotion to the present and future welfare of the Medical Department;

Resolved, That Professor Richardson, endowed by nature with physical, mental, and moral superiority, was pre-eminently distinguished for his culture and skill as surgeon and physician, which gained for him national reputation and rendered him one of the most instructive and popular of medical teachers; for exceptional scientific attainments, which, while broadening his views of nature's God, left him none the less firm in his Christian faith; for his courage and patriotism in war and his benevolence and philanthropy in peace; for his moderation and wisdom in council, and for his zeal and ability in executive administration; for his inflexible devotion to truth, honor, and duty; for the strength of his friendships in adversity as in prosperity, and for the fidelity, tenderness, and devotion given to his beloved and honored wife.

Resolved, That by the death of this strong, wise, and good man the medical department has lost its most valued friend and counsellor; the medical profession its most honored representative in New Orleans; the State of Louisiana a citizen unsurpassed for patriotism and for worth; his friends a heart to love and a hand to help them, and his wife and family one who has left precious memories of a loving, virtuous, and noble life.

Resolved, That at the next Annual Commencement, April 5, 1893, memorial addresses upon the life and services of Professor T. G. Richardson, M.D., shall be de-

livered. —Stanford E. Chaille, M.D., Dean, Medical Department, Tulane University of Louisiana, New Orleans, La., May 30, 1892.

College Commencements.—The Detroit Medical College graduated a class of 51 on March 22d. The Michigan College of Medicine and Surgery graduated a class of 34 on March 15th. The Medical Department of the University of Pennsylvania held its one hundred and eighteenth Annual Commencement on May 6th, and conferred diplomas on one hundred and fifty-four graduates.

The Medical Colleges of the United States.—The following table has been prepared from the Report of the Commissioners of Education for the year 1888 89:

	Number of Schools.	Professors and Instructors.	Students.	No. of Graduates at Commencement of 1889.	Amount of State or municipal aid received within a year.	Benefactions.
Regular	92	1,907	12,338	3,296	$24,820	$87,139
Eclectic	9	116	669	186	.....	5,200
Homœopathic	14	249	1,159	312	25,000	16,004
Physio-medical	1	11	15	5	.....	200
Post-Graduate	7	261	909	25	.....	19,600

—*Medical Age.*

A Hint for New Jersey.—To rid the house of mosquitoes, evaporate gum camphor in the room by placing a piece in a plate and holding it over a lamp until the fumes penetrate the room.

The Metric System.—In the new United States Pharmacopœia, now in course of preparation, the metric weights and measures will be adopted throughout, to the entire exclusion of the English weights and measures hitherto used.

Society Meetings during June.—June 1st, Ontario Medical Association, at Toronto; June 2d, Oregon State Medical Society, at Portland; June 2d, Rhode Island Medical Society, at Providence; June 2d, State Medical Society of Arkansas, at Little Rock; June 4th, American Academy of Medicine, at Detroit, Mich.; June 7th, American Medical Association, at Detroit, Mich.; June 7th, Massachusetts Medical Society, at Boston; June 8th, South Dakota State Medical Society, at Salem; June 14th, Medical Society of Delaware, at Dover; June 15th, Minnesota State Medical Society, at St. Paul; June 20th, American Association of Andrology and Syphilology, at Richfield Springs, N. Y.; June 20th, New Hampshire Medical Society, at Concord; June 21st, Colorado State Medical Society, at Denver; June 22d, American Neurological Association, at New York; June 28th, Medical Society of New Jersey, at Atlantic City.

Infection by Telephone.—The possibility of infection by the use of the telephone mouthpiece by successive speakers has been hypothetically discussed before now. A correspondent of the *British Medical Journal* brings forward some facts in support of the possibility of such an occurrence. Dr. Anderson, the Medical Officer of Health for Dundee, who has had the matter submitted to him, has given a very sensible answer, which sums up the position in a practical manner: "If a person who is suffering from sore throat of an infectious nature brings his mouth into close, or even near, relation to the mouthpiece of a telephone instrument, I think, in the act of speaking and expiration of air from the lungs and throat, it is possible that infectious particles might adhere to the instrument. I think an instrument which is so much exposed to the human breath should be frequently cleansed, whether the instrument be in a public or private room, and perhaps the simplest and most convenient cleanser is warm water and carbolic or sanitas soap."

The Intercolonial Medical Congress of Australasia is to be held in the grounds and buildings of the University of Sydney during the week commencing September 26, 1892.

A Curious Example of Applied Science has just been recorded by Mr. Marmaduke Sheild. A plumber, while carrying a pot of molten lead, fell, and some of the liquid metal splashed into his ear, causing indescribable agony, as may well be imagined. After the immediate effects of the injury had passed off, it was found that the metal had burst through the tympanum and filled the tympanic cavity, the surface of the lead being just flush with the remains of the drum. It had also penetrated the Eustachian tube and the various depressions in the middle ear, so that removal by the ordinary means was impossible, so tightly impacted was the mass, in spite of the most patient and persevering efforts. It then occurred to the ingenious operator to try the effect of solvents, and mercury at once suggested itself as a possible agent. Experiments having satisfied him of the feasibility of the process, a quantity of metallic mercury was introduced into the ear and retained there for some time. Altogether the treatment was kept up for about sixteen hours, and the success of the experiment was soon testified to by the escape of some of the mercury along the Eustachian tube. Ultimately, an energetic syringing brought away, first, some of the *débris*, and then the mass itself. Mr. Sheild may with justice congratulate himself and his patient on the success of his ingenious plan of treatment. —*Hospital Gazette.*

"Vitaline."—A Russian quack introduced into use a secret remedy which he called "vitaline." It had the power of rejuvenating the old and curing the young. It became immensely popular, and over ten thousand people received the injections. Finally a patient died, the quack was arrested, and confessed that his remedy was only borax and glycerine.

Ernst Brücke's Last Works.—The celebrated physiologist, Ernst Brücke, who died not long ago, had to resign his professorship in Vienna in 1890, in accordance with the statutes of Austrian universities, which require the retirement of professors who have completed their seventy-first year. The time thus placed at his disposal was spent by him in writing two books, one entitled "Schönheit und Fehler der Menschlichen Gestalt ("Beauty and Defects of the Human Form"), which appeared in 1891; the other, "Wie Behütet man Leben und Gesundheit seiner Kinder?" ("How can one Guard the Lives and Health of one's Children?") which appeared after his death.

A State Asylum for Epilepties.—One thousand epileptics are expected to enter the Asylum for Epileptics now being erected at Gallipolis, O. This is said to be the first institution of the kind erected in this country.

Society Reports.

American Medical Association.

FORTY-THIRD ANNUAL MEETING.

Held in Detroit, Mich., Tuesday, Wednesday, Thursday, and Friday, June 7, 8, 9, and 10, 1892.

(By Telegraph to the MEDICAL RECORD.)

FIRST DAY, TUESDAY, JUNE 7TH—GENERAL SESSION.

THE opening session of the Forty-third Annual Meeting of the American Medical Association was held in the Detroit Opera House on the Campus Martius. The meeting was called to order at eleven o'clock by DR. H. O. WALKER, Chairman of the Committee of Arrangements.

After a prayer by the RT. REV. THOMAS F. DAVIES, Episcopal Bishop of Michigan, a brief address of welcome was delivered by GENERAL R. A. ALGER. The speaker expressed the pleasure which he felt welcoming to Detroit and Michigan the members of this great Association. The city was glad to receive them, every door was open to whomsoever sought admittance. The people would do all that lay in their power to make the stay of the visitor a pleasurable one. If any of the medical guests did not see what he wanted, he had only to send for it, and if he did see what he wanted, he was to take it.

DR. WALKER supplemented this address by a few words of welcome from the medical profession of the city, whose honor it was to entertain for the third time the American Medical Association. He then introduced the President of the Association, DR. HENRY O. MARCY, of Boston, presenting him at the same time with a handsome gavel made from the wood of the celebrated Pontiac tree, a tree which was the silent witness of the final triumph of the infant settlement of Detroit over its savage foes.

THE PRESIDENT thanked the committee for its gift, and said that he felt a peculiar pleasure in being able to reciprocate by presenting to the Association a gavel with other and no less precious historic associations. It was made from a piece of the Charter Oak of Hartford with a handle of wood from the United States frigate Constitution. Armed with those two symbols of authority, he entered with no misgivings upon the honorable task of guiding the deliberation of the representative assembly of the physicians of the United States.

Evolution in Medicine was the title of the President's address. The American Medical Association, he said, holds a position among the great medical societies of the world in many ways unlike that of any other. Born of a felt want among the members of a profession widely scattered in a comparatively new and imperfectly developed country, it struggled along in the weakness of its infancy, conquering the disadvantages of great distances, compassed by comparatively slow, tedious, and expensive means of travel. It was wisely enacted that the Association consist in a large degree of delegated membership, since this makes it, as by no other plan, a representative body, and he thought that it was not too much to claim that it stands as the exponent of the medical thought and progress of the profession of the United States.

Although the speaker held that the Association must have its own inherent law, its Code of Ethics, he inclined strongly to the side of liberality, and believed that the differentiation between so-called schools of medicine should be made alone between ignorance and knowledge, since it is only fair to grant that considerable classes of men devoted to a common calling must be adjudged alike honest, and that their own selfish interest in the attainment of success in any given profession must be determined by the adaptation of the best means to a given end. Such differentiation means the abolition of ism and pathy, and there will be introduced in their stead a more or less accurate interpretation of scientific law as to what constitutes the treatment of disease, of which year by year there is the constantly increasing demonstration that the mere administration of drugs, no matter how valuable, is the least important part.

The rise of homœopathy as a separate school of medicine was due in great measure to the unreasoning and dogmatic opposition of an exaggerated conservatism, one effect of which was to arouse public sympathy for the advocates of the new theory, who were thus placed in the position of the under dog in the fight. In Europe, where the new doctrine was given a chance to prove its superiority, it has made little or no way among the people or in the universities.

The speaker then referred to the anomaly of two distinct State societies in New York, which, however, has had the good effect of stimulating both societies to the accomplishment of excellent scientific work.

The Relation of the American Medical Association to the General Profession in America.—There has arisen, even among the warm supporters of the American Medical Association, the inquiry if the larger service of the organization to the profession at large had not been accomplished, coupled with the criticisms that our country is far too great, and extending over too much area, for any one central body; that the development of our art has grown beyond the possibility of personal compass; that this is the age of specialism; and that the evolution of the medicine of the future must, of necessity, be in the hands of special societies devoted to the perfecting of certain lines of investigation. In the recognition of a common want there have been formed national societies, limited in membership, covering all the special branches of medicine and surgery. Under the leadership of a few master spirits it has been thought quite sufficient to bring these special societies together at repeated intervals under the attractive title of "The American Congress of Physicians and Surgeons." All this, Dr. Marcy said, met his approval, but he could not help thinking that such an argument was founded on a false conception of our professional duties and their relation to our life work; since, regardless of the specialistic development to which we may subsequently attain we must begin upon a common level and master, with greater or less fidelity and patience, the fundamental branches of medicine; and he who does this well and perfects himself most broadly and deeply in a general way, in practice as well as theory, finds himself subsequently the better fitted for specialistic labor. In the general field of medicine the great rank and file of the profession must continue to work, and as the representative body of this vast army of workers the American Medical Association, without fear or favor, must continue to be its exponent. Here, as upon a common altar, the most obscure may bring his offering and find inspiration which will help to make him subsequently a leader in some one of the many fields of specialistic research and a contributor to the resources of his profession in such a way that we will gladly entwine about his brow the laurels of immortality. There is no occasion for jealousy between the national societies of our great country. The field is large and the work ample.

The speaker then dwelt upon the relation of the Association to the State societies, the annual meetings, the labors of the Sections, and the work accomplished by the *Journal* of the Association.

The Evil of Intemperance was touched upon briefly, the matter being one which concerned so closely the members of our own profession, than whom none are better qualified to instruct the public upon the uses and abuses of intoxicating liquors.

A National Board of Health.—As to the question of a National Board of Health, the speaker regarded it as one of great importance. It had been urged, with reason, and he trusted that it would soon be carried into effect, that not only such a wisely selected National Board of Health

should be re established by the general Government, but also that it should find its exponent in a specially appointed member of the Presidential council to be known as Secretary of the Public Health. In the United States such an organization is not only more necessary than in any other country, on account of its widespread geographical area and population existing under more diverse conditions, but also because the medical officers of our Government, in both the Army and the Navy Departments, are much less in number than those of the European nations. We are deeply indebted to the American Public Health Association for the exceptional work which has been accomplished under its auspices in the advancement of sanitary science and the practical application of public hygiene. Its publications have proved a very efficient means for the dissemination of valuable knowledge. The work of the Department of Agriculture had given great satisfaction, and its field of usefulness was about to be extended by a bill now pending, which has for its purpose the protection of the public from the adulteration of food products in the United States. It is an important subject, an effort made in the right direction for the protection of the people from stupendous frauds and imposture, resulting in great injury to the community, oftentimes fraught with the gravest dangers to life, and it should meet with the heartiest approval and active support of our entire profession. The food products presented for sale in our markets should be reasonably safe for public consumption, as assured by Government inspection.

The Relation of the Association to the Medical Profession in Foreign Countries was a cause of much satisfaction. At the Berlin Congress there were over six hundred and fifty members from the United States, the largest number representing any nationality except Germany. The great majority of these were delegates from this Association. The speaker then referred to the Pan-American Medical Congress, and said that if our nation fulfils its apparent destiny, the early future will see no longer the necessity of our advanced pupils making European pilgrimages for original research and study in foreign languages, but rather that our own great centres of learning will be selected as the Meccas of the best modern thought, where students of all nationalities shall gather for instruction. Professor Virchow, in his presidential address before the last International Medical Congress, congratulated the surgeons of America as at present representing the best attainment of surgical teaching and practice in the world. It is not too much to claim that we are now equipped to compete successfully with any of the great centres of European learning for the teaching of medicine in all its numerous branches, and few more potent measures can be advocated, for the better union of all our Western interests and the moulding of the scientific thought, in its various branches of learning, of the leaders in this coming civilization of our great Southern continent.

Consumption.—The fell destroyer consumption is the greatest scourge of the human race, counting its victims, in the United States alone, over one hundred thousand annually. We have the clear demonstration of its cause, as a particulate morbific entity, with its life history and development now clearly established; how it enters the human organism, and by its propagation and development results in the death of the individual. The discovery is sufficient honor to one man, we might almost say to one generation, since, based upon such knowledge, there must develop means for its control, if not its extermination. "A nation's health is a nation's wealth," a nation's happiness. The application of the principles of modern science, as already known to us, introduced into the practice of daily living, would diminish sickness and suffering one-half and the death-rate by at least one third. It is for the medical profession to show how these principles may be applied and how this scourge may be deprived of its terrors. It becomes us, as a great high priesthood of the most sacred calling, veritably as Moses to an enslaved people, to point out the way of life, its dangers, and how to avoid its accidents, and to direct in the great highway of human endeavor the development and fruition of the human race, a training of the soul's pupilage for immortality—*Mens sana in corpore sano.*

The address was referred with the thanks of the Association to the Committee on Publication.

Dr. Gihon reported the death of Dr. Brodie, of Detroit, ex-president of the Association, and moved a vote of condolence to the family.

Dr. Bray Prest, of the Canadian Medical Association, was then introduced and extended a cordial invitation to all members of this Association to attend the meeting of the Canadian Society at Ottawa, September next.

The Report of the Secretary was then read by Dr. Atkinson. It dealt chiefly with the question of representation in the Association, a subject which presented many difficulties owing to the diverse laws of the societies in the different States. The speaker proposed action leading to greater uniformity in respect to membership in the various State and local medical societies.

It was voted that the question of representation of the Mississippi Valley Medical Society be referred for decision to the Judicial Council.

Report of the Committee on Sections.—Dr. Marshall, of Chicago, read the report of the Committee on Sections which had been appointed to devise means for improving the work of the various Sections. The Committee advocated that more time be given to Section work by shortening the general sessions. In order to effect this it proposed an amendment to the Constitution, to the effect that an executive committee of three members from each Section be appointed to constitute a general business committee, to which shall be referred all new business introduced in general session, and which shall also take the place of the Nominating Committee. The amendment was moved as a substitute to the one introduced by Dr. Culbertson at the last meeting. The report of the Committee was adopted. It was objected that this proposed substitute to the amendment involved such radical changes in the organization of the Association, taking away entirely its representative character, that it should not be considered this year, but should lie over as a new amendment. A motion to lay on the table was lost. The Chair decided that the substitute should lie over for one year, but on appeal his decision was not sustained. It was then moved to amend by striking out the clause relating to the Nominating Committee, and the amended substitute was then adopted by a two thirds vote.

Secretary of Public Health.—A long report of the Committee on Secretary of Public Health was then read. The Committee reported progress, asked to be continued, and begged that physicians throughout the country urge the consideration of this measure upon their representatives in Congress. After a protracted discussion the report of the Committee was adopted.

Although there were several committees yet to report, it was so late that an adjournment was had, in order not to encroach upon the time allotted to the work of the Sections.

The attendance at this meeting, to judge from the large audience at the opening session, is greater than for several years previous. The house was well filled by the delegates and their wives, while the familiar faces of many of the older and venerated leaders of the Association were visible on the stage. In addition to this the stage was further ornamented by graceful palms and hydrangeas, and other potted plants.

In the evening a reception was tendered the members of the Association and their ladies, at the Light Infantry Armory, by the medical profession of Detroit. The lady visitors were also entertained by carriage drives around the city and yacht sailing on the river in the afternoon.

SECOND DAY, WEDNESDAY, JUNE 8TH.

The session was opened at eleven o'clock by the President.

After the announcement of meetings of special committees and sections, the Secretary read a resolution offered by DR. HOUGHTON, of Vermont, calling for the appointment of a committee to consider the changes, if any, that it may be deemed necessary to make in the Code of Ethics. On motion this resolution was adopted.

The Judicial Council then reported upon the question of membership of Dr. W. W. Potter, of Buffalo. The Council reported that the New York State Medical Society and the Erie County Medical Society are not in affiliation with the American Medical Association, hence Dr. Potter, as a member of these societies, cannot be recognized as a member of this Association.

DR. REYNOLDS, of Kentucky, moved to refer the report back to the Council for consideration.

THE PRESIDENT decided that the question was out of order. An appeal to this ruling was taken, but the President was sustained.

For a time the Convention was in the utmost disorder, and a very serious quarrel seemed to be imminent; but, thanks to the firmness and intelligent guidance of the presiding officer, peace was finally restored. Although the delegates voted by a large majority to sustain the President's ruling, it was evident that very many of them were not in sympathy with the action taken by the Council in depriving Dr. Potter of his right to membership.

DR. C. A. L. REED, of the Committee on the Pan-American Medical Congress, reported progress.

At the conclusion of Dr. Reed's report DR. VANDERVEER, of Albany, rose to a question of personal privileges. He said that he and a number of his colleagues, members of the New York State Medical Society and permanent members of the American Medical Association, wished to know where they stood. They had been invited here by officers of the Association and had been asked to read papers, and now one of them had been declared not to be a member of the Association. They were thus placed in a very embarrassing position.

DR. REED, of Ohio, moved that the question of the status of the permanent members from New York State be referred for consideration to the Judicial Council.

This was followed by a long discussion and the introduction of several substitute motions.

It was moved as a substitute by DR. KING, of Missouri, that the President appoint a committee of five to meet with a like number from the Medical Society of the State of New York, to adjudicate upon the standing of members of that society, and report at the next annual meeting.

An amendment was offered to this by DR. GIBSON, of the United States Navy, that until this report was made all the permanent members from New York State now registered retain their privileges in the Association.

A further amendment was introduced by DR. TRUAX to the effect that five members from the New York State Medical Association be added to this Conference Committee.

The substitute motion and its three amendments were finally carried unanimously.

Address on Surgery.—DR. JOHN B. HAMILTON then delivered his address, the subject of which was "The General Principles of the Surgery of the Brain and Its Envelopes." There is an old axiom, the orator said, to the effect that there is no wound of the head too small to be despised, and none too grave for life to be despaired of. In spite, however, of this, the general rule has been, until recently, to rely in most cases of cranial injury upon the *vis medicatrix naturæ*.

The speaker then reviewed the history of cerebral surgery from the earliest times down to the present. Some progress has been made in operative measures, especially in the use of the surgical engine, but the most marked advance has been in the line of diagnosis of intra-cranial lesions. The use of the phrase cerebral localization was condemned, the speaker holding that the single word diagnosis was sufficiently comprehensive. In the case of abscesses as well as of gun-shot injuries the diagnosis is often extremely difficult. The localization of critical lesions is often comparatively easy, but that of affections of the cerebral ganglia is a matter of extreme uncertainty. What is most feared after an injury to the skull is the formation of cerebral abscess. This, it should be remembered, may follow a simple fissure almost as readily as a more extensive wound. The deeper parts most remote from the surface are most liable to be the seat of a suppurative process, owing to the difficulty of cleansing them and freeing them from particles of foreign matter. Intra-cranial hemorrhage is another danger to be apprehended. The speaker then quoted the reports of a number of cases of operation for traumatic hemorrhages, taken from recent literature. Trephining for aphasia after injury is not a very rare operation, but it has seldom been done when there was no external wound. The necessity of distinguishing between sensory and motor aphasia was insisted upon. In the matter of trephining, Dr. Hamilton referred to a recent paper by Dr. Roberts, in which the writer made a strong plea for conservatism, condemning what was called experimental operations. He insisted, however, upon the necessity of trephining in the case of punctured wounds.

Cerebral Injuries in the New-born.—Operative interference in these cases has been generally barren of results. The operation of craniotomy for the relief of intra cranial pressure and microcephalus was referred to, and the reports of some cases read. Spinal laminectomy—as recommended by Mr. Luke for the relief of intra-cranial pressure from accumulated cerebral fluid—was mentioned with approval. The writer believed it was worthy of a trial in suitable cases before a resort was had to craniotomy, for the reason that the further removed from the head was the point of operation the greater the safety to the patient. The ancient practice of trepanning for epilepsy has lately been revived in certain cases, with apparent benefit; but the cases ought to be carefully selected, and indiscriminate operation was to be condemned. The speaker then referred briefly to certain recently performed operations on the cranial nerves, especially to the removal of the Cæsarian ganglion for relief of inveterate neuralgia, and to Hartley's intra-cranial neurectomy.

In conclusion, Dr. Hamilton said that, although the progress in cerebral surgery had been considerable, there yet remained much to gain in this field. What had already been accomplished was due in the first instance almost wholly to the labors of Pasteur and Lister, which had resulted in the universal adoption of antiseptic surgical methods.

On motion the address was referred, with the thanks of the Association, to the Committee on Publication.

After the reading of some notices by the Secretary, Dr. Atkinson, the session was then adjourned.

THIRD DAY, THURSDAY, JUNE 9TH.

Annual Report of Rush Monument Committee.—DR. GIHON then presented the annual report of the Rush Monument Committee. A contribution of $300 from the exhibitors at the Nashville meeting had been received. Nearly $600 had been contributed by the county societies in Pennsylvania. While other offerings had not been so liberal, yet the Committee was in a position to state that a memorial would be erected, the question now being simply one of the size of the monument, whether it should be a full-length statue or a modest bust.

A resolution was passed endorsing the efforts of the Association of Medical Colleges to raise the standard of professional education.

The Journal of the Association.—The report of the

trustees of the Journal was then presented, and, after some discussion, accepted.

The Committee on the Jenner Centennial recommended that the Association devote one day during the meeting in 1896 to eulogies, papers, and volunteer essays on Jenner and the practice of vaccination.

The Address on General Medicine was the next business in order. Some delegates attempted at this point to renew the quarrel of yesterday over the question of membership of the New York men, but were not encouraged by the rest of the body.

Dr. Alfred L. Gihon, U. S. Navy, took as his subject "Intellectual Progress in Medicine." The most gratifying outcome of the year was not the announcement of new therapeutic means nor the publication of nosological novelties, but rather the steadily rising standard of medical editorship. He urged an earnest countenance and substantial support of medical literature, not merely by subscribing for the journals, but by contributing to them. The specialty of medical journalism requires the highest order of ability, the broadest culture, and the widest range of information, if it is to be successfully prosecuted.

As compared with other branches of journalism the speaker believed that medical periodicals were more widely read and their contents were more carefully scrutinized, while their editorial leaders, notes, and criticisms are more independent, fearless, and unbiased. Dr. Gihon also congratulated the Association upon another sign of the progress of the day in the reform of medical education. A minimum of three full courses, in many schools four, and these consequent upon prerequisite academic or collegiate tuition, expressed in one university as six years of continuous college tuition for the intending physician, is a prouder achievement in medicine of this year 1892 than all the additions to its Pharmacopœia or all the refinements of its therapeutic theories.

But the duty of the physician does not end with supporting and contributing to medical journals, and with encouraging reform in medical education. He should be in active fellowship with one or more medical associations, but he should not confine himself to these. The physician should be the first citizen of the commune, the peer in education and culture of the highest, and a leader in all the sociological and political movements of the day.

Dr. Gihon then alluded to the strange lack among the profession of hero-worship, when the heroes are its own. He thought it would be unpardonable to neglect to give due credit to the bacteriologists.

The orator then referred to a paper read by Dr. Sternberg at the last meeting of the Association of American Physicians in Washington, in which were detailed the results of recent discoveries concerning anti-toxines, which suggest the possibility of a new departure in the specific treatment of infectious diseases.

Officers for the Ensuing Year.—The Committee on Nominations has selected the following candidates: Dr. Hunter McGuire, of Richmond, Va., *President;* Dr. H. O. Walker, of Detroit, *First Vice President;* Dr. H. Brown, of Kentucky, *Second Vice President;* Dr. H. Janes, of Vermont, *Third Vice Presiaent;* Dr. Jesse Hawes, of Greeley, Col., *Fourth Vice President;* Dr. R. J. Dunglison, of Philadelphia, *Treasurer;* Dr. W. B. Atkinson, of Philadelphia, *Secretary;* Dr. Montgomery, *Assistant Secretary;* Dr. George W. Webster, of Chicago, *Librarian.* To fill vacancies on the Board of Trustees: Dr. Alonzo Garcelon, of Lewiston, Me.; Dr. Leartus Connor, of Detroit; Dr. Perry H. Millard, of Minnesota, and Dr. Patterson, of Washington. Members of the Judicial Council: Dr. N. S. Davis, of Chicago; Dr. John Morris, of Baltimore; Dr. H. D. Didama, of New York State; Dr. John B. Roberts, of Philadelphia; Dr. A. M. Emmert, of Iowa; Dr. W. T. Briggs, of Nashville, Tenn.; Dr. C. W. Voorhes, of Coldwater, Mich.; Dr. W. E. B. Davis, of Rome, Ga.; Dr. A. Morgan Cartledge, of Louisville.

Milwaukee was chosen as the next place of meeting.

SECTION IN PRACTICE OF MEDICINE.

(By Telegraph to the Medical Record.)

First Day, Tuesday, June 7th.

The Relations of Bacterio-chemical Results to Prophylaxis and Therapeutics was the title of a paper by Dr. Robert T. Edes, of Jamaica Plain, Mass. The great progress of the year had been along the line of investigating the poisons which are the result of germ activity, their nature, and their effects. It has been shown that many germs produce an alkaloid, and as well a poisonous albumin or albumose. Fever itself was undoubtedly the result of some such substance which acted by its influence on the heat-centres.

Researches also had recently been carried on regarding the absorption of nitrogen by plants from the air. It had always been supposed that this element was derived from the soil in plant formation; but certain plants, especially the bean family, can grow in a soil entirely devoid of nitrogen and yet form nitrogenous compounds. This property seemed to depend on the presence on the plant, or rather on its surface, of a certain bacillus.

Another most important topic which had received much attention during the year had been that of immunity. We had come to believe that much depended on the condition of the blood, either its fluid elements (possibly blood-germs) or the leucocytes, more probably the latter. Furthermore, the products of germ-action (toxine) seem, after reaching a certain degree of strength, to inhibit their own activity. An analogous illustration was seen in the power of a certain percentage of alcohol to check fermentation, though it was a product of the latter. Such a method was as yet unavailable in the human system. Koch's tuberculin was not to be condemned as a failure. It was an attempt along a line which is likely soon to witness a great and fruitful development. Closely allied to the doctrine of immunity is that of resistance to disease. We do not know why some persons can meet with impunity an exposure to which others would quickly succumb. Animals, if starved, will be overcome by an amount of bacterial poison without effect if they were properly nourished; and furthermore, over-feeding will enable them to withstand a much greater dose of the disease-poison. There is in each system a certain protective element which comes in contact with the product of our usual contagious diseases and destroys the toxines of the latter, thereby protecting the system from the further inroads of the same kind of poison, but rendering it more liable to succumb to other kinds. So far as treatment was concerned, emphasis was to be laid on two special points. There was great danger from the flesh and milk of tubercular animals. There was not, in the writer's opinion, much risk from mere association with phthisical patients. The latter should be cautioned against scattering their sputa around. Special attention should be paid to nutrition and climate. So far as the latter had reference to lung cases, a lofty, dry place was preferable, because the air was relatively free from germs. It also acted as a general tonic, and the increased pulmonary activity it occasioned was in itself a favoring circumstance.

All of these questions had to be looked at from a different stand-point so far as the scientific worker was to be compared with the chemical student. The problems of the sick-room were not those of the laboratory. It was difficult to free clinical work from personal errors, but we should faithfully report our results, good or bad.

Immunity.—Dr. Kinsman, of Ohio, gave an account of some experiments which had been made in that State with reference to hog cholera. Immunity is, he thought, only a relative term. Our ideal should be absolute protection. Our present trouble is that our doses of remedies strong enough to kill the germ or inhibit the products of its life activity are also strong enough to harm the patient. In several of the Western States attenuated cultures of the hog cholera-germs were given to animals, with good results. They could then be pastured in fields

and thrive where uninoculated animals speedily died. The culture medium used in the experiments detailed by the speaker was sterilized human urine. The fluid inoculated was diluted to about one-sixth of its original strength, the cultures being kept at the blood temperature, and the sterilization of the urine being accomplished by the usual methods. The fact was that in many of our investigations we did not know exactly what the cause of disease was, and hence, while we approximated toward perfect immunity, we could not quite reach it.

Dr. W. J. Scott, of Cleveland, O., thought there was some doubt as to whether in our dilution by attenuated virus we are not also altering the nature of the poison, so that we have to deal with a morbific principle different from the one which is the result of the first generation of germs. As regards the effect on the body temperature, anything which disturbs the relations of the system and the products of nutrition and waste will cause increased chemical activity, and that we know is always a source of heat.

Dr. Denison, of Colorado, had recently received a letter from Koch, of Berlin, in which the latter disclaimed ever having admitted that tuberculin was a failure. The speaker himself had unbounded faith in its future. He also alluded to recent experiments made with a piece of the thymus gland as a culture fluid. Tetanus germs had in fourteen days been rendered from three to five thousand times less powerful than the original cultures.

Dr. Greenwood, of Kentucky, did not believe that hog cholera was altogether a contagious disease. It would skip about from one farm to another in a given locality, while animals on intervening farms were not affected. In one instance live hogs ate the bodies of their kind who had died of the cholera, and the disease was soon checked in the entire drove.

Dr. S. P. Kramer, of Cincinnati, reviewed the work which had been done by German observers during the past year with reference to immunity, laying special stress on the nature of the "anti-toxines" developed by adding to the blood of an animal one of the peculiar albumoses produced by bacterial action. If we could isolate the latter by injecting it, we could with the aid of the union with the blood cause immunity. In these experiments on animals there is always danger that the attenuation product may revert to its original type, and so offer no stay to the ravages of disease. It was interesting to know that if goats were thus rendered immune to tetanus, the immunizing principle appeared in the animals' milk.

Etiology of Specific Disease.—A paper with this title was read by Dr. R. French Stone, of Indianapolis, Ind. It was a historical review of the various theories which have prevailed in times past with reference to the exact nature of specific disease. He took strong ground against the wholesale acceptance of the present products on the germ theory of disease.

The paper was discussed by Dr. Hoyt, of Detroit.

Recent Investigations of the Etiology of Diabetes Mellitus was the title of a paper by Dr. S. P. Kramer. No less than twenty-seven theories had been put forth with reference to the cause of diabetes; it had been found that the pancreas was at fault in fully one-half of all the cases. The removal of the organ in animals was always followed by the malady. If it was partially removed, the disease remained absent, providing one-tenth of the original bulk of the organ was left *in situ*. Ligature of the duct gave negative result. These results seen in dogs were duplicated in cats and swine, but not in birds. In dogs in whom the malady had supervened after the removal of the organ, if they were fed on pancreas no relief ensued, but the latter did follow if bits of the organ were transplanted back into the anterior abdominal wall; if they were fed on glucose it was used up in the system and none excreted, but not so with condose. As the result of a long series of experiments, Dr. Kramer expressed the belief that the organ supplied to the blood a glycolitic ferment by which the sugar in the blood was destroyed, but if the viscus was removed the absence of the ferment, which resided chiefly in the white cells of the blood, caused the glycosuria. He did not offer this as an exclusive view, the ferment was found in the blood at its maximum four or five hours after removal from the animal. Normally, the sugar of the blood combines with some albuminous principle therein for the general benefit of the system. In diabetes this does not take place.

Hepatic Abscess.—Dr. George E. Fell, of Buffalo, related a case of hepatic abscess in diabetes. The pus eventually opened into the gut and the diabetes disappeared. This was evidence, in his opinion, that lesions of the pancreas were not the only factor in etiology.

Dr. S. Solis-Cohen, of Philadelphia, quoted the division of diabetics by a recent French writer into thin cases and fat cases. The pancreatic cases were in thin people, but not in the fat people. There was still another form, related in some way to the uric acid diathesis. Moreover, nowadays, the polydipsia and polyuria were more dreaded than the glycosuria. There was a malignant combination of the two former causing fatal result even with no sugar. There was probably a group of cases here alike clinically, but differing in their etiology.

Influenza.—Dr. John E. Link, of Terre Haute, Ind., read a paper on "La Grippe," in which he took the ground that the disease was not a germ disease, but one spending itself principally on the pneumogastric centre in the medulla. He thought that all the various aspects of the malady could be explained by this view. He had noted many cases with a peculiar paleness of the face, a milky whiteness of the tongue, and great prostration, with occipital pain, even before any active grippal manifestations came on. They had all yielded promptly to quinine and opium, but after recovery, if the former drug was stopped too quickly, they suffered severe relapses. Dr. Link doubted whether there were any real inflammatory or congestive properties belonging to true grippe. He believed that we might have an inflammatory neurosis, say of the lung and bronchial tissue, with abundant serum, but it was not pneumonia. In many cases the outpouring of serum into the air-cells led to the death of tissue and abscess formation. The physical signs were not like those of pure pneumonia. There was a loud, moist râle in addition to the crepitation of pneumonia.

A Modified Form of Continued Fever following the Epidemic Grippe, was the title of a paper read by Dr. John H. Hollister, of Chicago, Ill. This disease had seemed to increase the severity of all our endemic maladies. He had observed, following the epidemic, many cases of continued fever which had been admitted to hospital classified as typhoid. He soon began to doubt the correctness of the diagnosis. A study of fifty cases had afforded the following data: No common cause could be assigned. Previous history was negative. Some had had grippe, but the majority not. The prodroma lasted four days, with extreme muscular soreness. The onset was gradual, no chill being noticed, but the fever was continuous without intermission. The average duration was twenty-three days. Relapses were common, but could be attributed in many cases to dietetic errors. There were no head symptoms or coma, and no subsultus. In four cases there was profuse sweating, lasting over ten days. The stomach was not troublesome. Secretions were all diminished, and there were not cutical discharges. The mouth was rarely dry, tongue not fissured, and no sordes. The dorsum was milk-white. There was no tympanites or abdominal tenderness; no peritonitis, while the bowels were bound up. In only three cases did the stools suggest typhoid. No bacteria were found in the stools. The urine did not respond to the Ehrlich test, nor were any albumin, sugar, or casts found. There was no rash. Dr. Hollister did not believe that the disease was typhoid. In treating the cases main reliance was placed on sponging and packs. Three cases died, one from pneumonia and two from exhaustion. No intestinal lesions were found at any of the autopsies.

The paper was also discussed by Drs. Didama, of Syracuse; Cronyn, of Buffalo; Hemenway, of Illinois; Davis, Jr., of Chicago, and Wilson, of Michigan.

Second Day, Wednesday, June 8th.

Positive and Negative Medication.—A paper with this title was read by Dr. Bedford Brown, of Alexandria, Va. More or less deaths occurring in practice are due to the incompetency of physicians, the incurable nature of given disease, careless nursing, and the adulteration and substitution by dishonest pharmacy. A point of primary importance is to assure ourselves of the solubility in the stomach of the remedies we use. On this account pills and capsules are often objectionable. Not infrequently they pass through the system and are found unchanged in the dejecta. Furthermore, in all fevers and in many other states the solvent power of the secretions is greatly lessened. Dr. Brown uses only glycerine or honey as excipients for pills, and gums of all kinds are open to the same charge of insolubility as sugar and gelatine. Often we must use solutions, and if these are not well borne, resort to rectal medication. Here mucilage offers itself as a proper vehicle for quinine when the latter remedy is indicated. The cold bath in high temperatures may often further and increase the absorptive power of the system. Moreover, one should see to it that when we order infusions and decoctions, the latter are made out of pure materials. We should avoid cheap drugs, because that very cheapness is a confession of inferiority.

Dr. H. D. Didama, of New York, used tablets and wafers entirely to the exclusion of pills. It was evident that dispensing by the physician was growing in both professional and popular favor.

Drs. Wilson, of Kansas City, and Herrick, of Cleveland, also commended the practice alluded to.

The Relative Inter-dependence of Organs in Health and Disease was the title of a paper read by Dr. Herrick, of Cleveland, O. He divided the various organs into three groups. In the first were the osseous, connective, and cellular tissues. In the second the circulatory, muscular, nervous, and reproductive organs; and in the third the organs of secretion, of digestion, absorption, assimilation, and excretion. The first was entirely passive, the second was active in securing the alternate end of life, and the integrity of the third was necessary for the functions of the second to be performed in a proper manner. The third group had for its alternate end the transformation of food stuffs into blood.

A Case of Amœbic Dysentery was reported by Dr. E. P. Gerry, of Jamaica Plain, Mass. It had until recently been believed that this disease was confined entirely to tropical countries, but the recent investigations of Osler, Councilman, and Löffler had shown that it was not unknown in northern latitudes. His patient was a single woman, aged twenty-five, who had been anæmic for a year. She began to have discharges from the bowels of blood-tinged mucus containing whitish lumps, and mixed with more or less brownish fecal matter. These were at first three or four in number daily, but later increased to eight or ten. Tenderness appeared in the right iliac fossa, and finally more or less tympanites with fever and some sweating. The discharges were painless, and appeared not to be affected by the nature of the injected food. The use of various astringents and zinc sulphate solution injections caused periods of remission. At a later period there was tenderness and thickening along the course of the ascending colon, with a hard lump to the right of the umbilicus and about midway between the costal cartilage and the anterior superior spine. There was no tenesmus. The stools were examined and numerous amœbæ dysentericæ were found. They were rounded or oval, with a diameter six or seven times that of a leucocyte. As the fæces had to be brought some distance for examination, the parasites were always motionless, even on a hot slide. The greatest relief was afforded by high rectal injections of quinine solutions 1 to 5,000. The patient finally succumbed to grippal pneumonia, and the autopsy showed the typical lesions described by Osler and Councilman.

Dr. Herrick, of Cleveland, doubted whether the amœbæ were always the cause of these symptoms. These might be often referred to disturbances in the hepatic circulation.

The paper was also discussed by Dr. Messer, of Cincinnati.

Retained Fæces was the title of a paper read by Dr. W. D. Christopher, of Chicago. Bowels apparently normal, often contained scybalous masses which could be brought away only by intestinal irrigation. These masses may cause peritonitis, local or general, typhlitis, and appendicitis. They may give rise to certain catarrhal states, in which the bacterium coli communis, ordinarily harmless, becomes exceedingly virulent. Of the poisons engendered by fecal retention a small amount may be destroyed by the liver, but if this organ is impaired or the dose of the poison is large, we may have the "stercoæmia," "stercoæmie" of the French writers. In using rectal injections the water should be warm. Several trials may be necessary before much fecal matter comes away. Iron and belladonna are a useful combination to enable the bowel to retain its healthy state.

Dr. N. S. Davis, Jr., of Chicago, believed that fecal retention was common in those whose bowels moved daily; these evacuations were merely nature's overflow and were utterly insufficient to empty the gut.

The paper was also discussed by several of the other members present.

The Transmission and Behavior of Typhoid Poison as Observed in Country Practice.—Dr. Lewis N. Davis, of Farmland, Ind., read a paper with this title. It was generally believed that water is the main, if not the only, channel by which the typhoid poison was conveyed, and that the germs in the stools were passive when they left the body of the patient; but in country practice there were many evidences to be had that the disease was contagious, and that it was conveyed by the air; also that the poison was virulent as it left the body. Several epidemics were quoted in support of this view.

The paper was discussed by Dr. Chapin, of Michigan, who thought that the views of the writer were correct, and by Dr. J. H. Musser, of Cincinnati, who did not think his conclusions were sound. He himself believed in transmission of the poison through drinking-water.

Catarrhal Gastritis was the title of a paper read by Dr. Harold N. Mayer, of Chicago. The term dyspepsia should be given up. It is a symptom and not a disease in itself. In chronic catarrhal gastritis we have too much mucus with a resulting impairment of digestive power. Out of 118 cases of gastric trouble, he had found 17 of uncomplicated gastritis (chronic) giving the usual symptoms in different combination and varying severity of epigastric pain, nausea, and vomiting. Less common were fulness, coated tongue, eructations, anorexia, vomiting, constipation, etc. As to etiology, the trouble is more common in males and users of tobacco, alcohol, and excess in iced drinks. The duration varies from months to years. The treatment is one of diet and but little medicine. Lavage had in his opinion but a limited value, because patients would not submit to it. He is in the habit of directing patients to drink from eight to sixteen ounces of very hot solution of bicarbonate of soda (ten grains to the pint) twenty minutes before eating. This removes the mucus and enables the food to come into direct contact with the mucous membrane of the stomach. Thereby normal peristalsis is set up. As to diet, a trial meal of lean meat and buttered bread should be given. As the patient improves, oysters, eggs, etc., can be added. Pastry should be avoided. Bismuth, cerium, nux vomica, and tonics can only be adjuvants; pepsin is good where there is atrophy of the

gastric tubules or organic structural changes; also in anæmic cases.

Dr. Stocton, of Buffalo, N. Y., regarded lavage as especially good for diagnosis, if not for treatment. Many of these cases are due to excess of hydrochloric acid, and such a condition must, of course, largely determine the nature of the diet. The stomach contents are often too long retained in that organ, and imperfectly digested, even where no symptoms are complained of.

Dr. Lyon, of Philadelphia, had found an absence of hydrochloric acid in many of these cases.

Dr. Hare, of Philadelphia, believed that the pepsin and soda mixture is often of service, because the acid required to enable the latter to act overcame the alkaline effect of the soda and aided digestion. We make the mistake of prescribing too much pepsin and too little acid. Bitter tonics, he believed, did more harm than good. Intestinal digestion was more powerful than gastric; hence we should give food rapidly passing into the bowels.

The paper was also discussed by Drs. Scott, of Cleveland; Porter, of Michigan; and Davis, Jr., of Chicago.

The Vertigo of Arterio-Sclerosis was the title of a paper by Dr. Archibald Church, of Chicago. This condition of vascular structure is the forerunner of true atheroma. The vertigo is often referable to dietetic errors and to various stomach disorders. It can be occasioned by suddenly rising from a recumbent position. It often is accompanied by staggering and in temporary aphasia, but not, in the writer's experience, by actual loss of consciousness. Patients frequently obtain temporary relief from baths, waters, etc. It is important to recognize the condition early, for, unless checked, it may eventuate in fatal cerebral hemorrhage. The diagnosis is often confounded with that of Ménière's disease (as the cases of vertigo often have an inclination to rotary movements, etc.) and arnal vertigo. As to treatment, he had found that iodide of potash (thirty to ninety grains daily) give the best results. Amyl nitrate and nitro-glycerine give but temporary relief, and their disagreeable effects are often more complained of by the patient than the disease itself.

On Some Non-valvular Heart-murmurs was the subject of a paper by Dr. N. S. Davis, Jr, of Chicago. Non-valvular heart murmurs may give the same physical signs as valvular ones, the same changes also in the size and position of the heart. Not infrequently we have cough, dyspnœa, vascular disturbances, œdema, urinary changes, etc. He related the histories of several cases in which the autopsy showed the cause of the murmurs to be old and tenacious decolorized clots in the ventricles and entangled among the chordæ tendinæ. In one case there was an old calcified plate of connective tissue (the result of a former pericarditis) in pericardium. The murmur in this latter instance was probably due to irregular muscular contractions in the ventricular walls, causing various eddies in the blood-current. Anæmia also caused murmurs not distinguishable in their physical characteristics from those of valvular lesions.

The Importance of Position in Examination for Diseases of the Heart.—The paper was read by Dr. O. B. Campbell, of Ovid, Mich. The anatomical relations of the diaphragm are fixed, but the apex may be bagged down from change of size of the heart. If the patient bends forward the apex-beat becomes more diffused transversely, but not vertically. He recommended recumbency in examining for cardiac disease, as he believed that the sounds became thereby more distinct. Out of 100 cases the murmur became more distinct in the recumbent position in 78; more distinct in the upright position in 6; not heard standing but developed on lying down, 4; unaffected by change of position, 12.

These papers were discussed by Drs. Kennedy, of Michigan, and Newcomb, of New York.

A paper on nutrition was read by Dr. Myrix J. Crouch, of Union, Ky.

SECTION ON SURGERY AND ANATOMY.

(By Telegraph to the Medical Record.)

First Day, Tuesday, June 7th.

Address of the Chairman.—Surgery of the Gall-bladder and Ducts.—Dr. J. McFadden Gaston, of Atlanta, Ga., referred to his experiments upon dogs, reported elsewhere, and considered the literature of the subject down to the present time. Surgery of the gall bladder was chiefly confined to the measures indicated in occlusion of the common duct. Where the duct was occluded by other cause than the impaction of stone, it was generally necessary to remove the gall-bladder. The dissection of its upper portion from the lower was a difficult procedure, and not unattended with risk, and he was accustomed to leave this portion of the bladder *in situ*. All obstructions by stone should be removed, and an opening only externally should be regarded as but a temporary expedient. Ultimately the gall-bladder should be united with the intestine. A biliary fistula established preferably with the duodenum. This was most desirable, though one with the jejunum might be hardly less useful. But with the colon the result was not satisfactory.

Obstruction of the Cystic Duct.—Dr. W. H. Myers, of Fort Wayne, Ind., reported a case, and said that stones might be present in the gall-bladder without pain, and that pain might be present without jaundice, but that when a calculus becomes impacted in the cystic duct the pain is always severe. The paroxysms of pain usually come on within an hour or two after the patient has taken food, and appear to be due to the natural effort of the gall-bladder to empty itself by the contraction of its muscular coat. In the case reported several stones were removed, and the opening in the bladder then stitched to the abdominal opening. Very little bile appeared on the dressings, but the fistula remained open. In similar cases the author would advise removal of the viscus.

Peritonitis from Gall stones.—Dr. W. E. B. Davis, of Rome, Ga., said that the risk from the rupture of the gall-bladder or ducts, and the extrusion of a gall stone into the peritoneal cavity, was from infection of that cavity by septic material from the gall-bladder rather than from the bile itself. Bile is not a septic fluid; it only causes peritonitis by its irritating quality, and only does this when in large quantity at the time of the accident. Poured out slowly, it sets up protective inflammations, the adhesions from which cut it off from the general peritoneal cavity. Peritonitis from the escape of gall-stones is very rare, and when it does occur it is usually due to the septic quality of the accompanying fluid. In his experiments upon dogs he had found that the bile did not excite peritonitis when allowed to escape into the peritoneal cavity. He had further found that packing the wound with iodoform gauze, left in three days, prevents peritonitis. He, of course, recognized the fact that the danger of peritonitis was greater from the presence of a gall-stone than in experimental work where only pure bile was allowed to escape. The chief point which he wished to make was the protection given by packing the part with iodoform gauze.

Discussion.—Dr. A. Van Derveer, of Albany, N. Y., said that he would not feel safe in leaving the anterior wall of the bladder as advised by Dr. Gaston. He then narrated a case from which he had removed sixty-four calculi. The external fistula remained open. Sometime later, when the patient died of tuberculosis, he found that the duct was closed. He favored medicinal treatment for a time, but if a case grows worse under such treatment he would then operate. In his experience, jaundice is absent in the majority of the cases of the paroxysmal; pain is the main symptom for which the surgeon must look. The chief danger in delaying the operative measures is the risk of perforation and a resultant septic peritonitis. Before closing the external opening, one must make sure that there is an opening into the intestine.

Dr. Marcy, of Boston, reported four unpublished cases, and advised early operation.

Dr. J. F. W. Ross, of Toronto, thought that one of the greatest risks was from the puncture of the intestine by the needle in suturing, and the consequent escape of the intestinal contents into the peritoneal cavity.

Dr Ferger, of Chicago, spoke of inflammation of the gall-bladder without obstruction to the flow of the bile, and believed that two operations to relieve the condition was a safer procedure than to attempt all at a single sitting.

Dr. Allen, of Cleveland, reported the case of a patient who had refused operation, and who died from the pain arising from the plugging of the cystic duct.

Gunshot Wound of the Liver and Stomach—Laparotomy—Recovery.—Dr. James T. Jelks, of Hot Springs, Ark., reported a case where the ball entered the left of the spinal column, just below the lower border of the ribs. The patient when seen had vomited much blood, and was in a state of shock. An opening was made from the ensiform cartilage to two inches below the umbilicus. Again the patient vomited blood, and the stomach with the ball was thrown out of the abdominal cavity into the operator's hands. Careful examination revealed no wound of the stomach, but a wound still bleeding was found in the posterior border of the liver. This was packed with iodoform gauze, the cavity washed out, the intestines returned with great difficulty, and a glass drainage-tube having been inserted, the wound was stitched up. Before union was perfect the abdominal wound broke open during a fit of coughing, and a knuckle of intestine protruded. This was replaced, and the patient went on to a good recovery at the end of three weeks.

Rupture of the Liver.—Dr Ferger, of Chicago, reported a case of rupture of the liver from a fall through an elevator shaft, where he found, a year later, that much hemorrhage had taken place without evil results.

Dr. Gregory, of St. Louis, thought that unless the plugging of the liver wound in Dr. Jelk's case had saved the patient's life, he would have lived without any operation whatever.

Dr. Thorn, of Toledo, reported a case of laceration of the liver left without treatment, where death occurred from loss of blood.

Dr. B. A. Watson, of Jersey City, said that he had often seen laceration of the liver in his experimental work upon animals, in which recovery had taken place after even a very large hemorrhage.

Dr. Griffith, of Kansas City, said that shock was not always present in these cases. When it was absent, what indications have we for operation if we are not to operate in all cases?

Dr. Walker, of Tennessee, reported a case in which there was shock at the time when he was called to see the patient, who declined operation, but who nevertheless died three hours later from hemorrhage.

Eight Cases of Œsophageal Stricture.—Dr. D. S. Campbell, of Detroit, reported seven new and one old case of œsophageal stricture treated by electrolysis. All made good recoveries.

Second Day, Wednesday, June 8th.

The Late Manifestations of Appendicitis and Their Treatment.—Dr. Dudley P. Allen, of Cleveland, reported six cases selected for the purpose of illustration and discussion, showing the different complications and dangers arising in cases which had escaped the primary attack of appendicitis. The cases cited included enormous collections of pus in the side, secondary abscess in the liver and lung, abscess involving the psoas muscle, extensive secondary abscesses of the thigh, and long-existing circumscribed abscess opening repeatedly into the intestine. The writer related his own experience in support of the fact of the dangerous character of appendicitis when left to follow its natural course, and was fully convinced of the correctness of the opinion held by American surgeons favoring operation in suitable cases, as against the more conservative view of a large number of European surgeons, who favor leaving the disease to medical treatment. The writer had operated upon a series of cases in which the patient had supposed himself to have suffered from repeated attacks of intestinal colic and had considered the beginning of the attack which finally led to operation of the same nature as those preceding, and the observation was well established that a large number of cases of appendicitis resulting in operation or in death had been preceded by other attacks of a less serious nature.

The question of the employment of salines as opposed to the opium treatment was discussed, more particularly in its reference to primary attacks of appendicitis than to those of a more marked nature, and, though the dangers of salines were recognized, a distinct advantage was claimed in that in certain cases when administered, they relieved the extreme tympanitis which sometimes occurs, rendering the operation difficult and seemingly destroying the patient after a successful operation had been performed, through the paralysis of the intestine, due to extreme distention. The extra-peritoneal operation was favored, where feasible; but, since by this method a certain proportion of small abscesses and perhaps foreign bodies might be overlooked, the trans-peritoneal method was advocated whenever necessary to the discovery of the seat of disease. As to the time of the operation, although its danger was recognized, and many surgeons hesitated in undertaking so serious an operation when the disease was seemingly quiescent, it was advised not to delay it too long in cases where the difficulty was recurrent, since the danger from recurrent attacks was considered greater than that of operation.

Desemoid Tumors of the Abdominal Walls.—Dr. Nicholas Senn, of Chicago, said that he had been unable to complete his work on the paper announced to be read by him, and begged to make a few remarks. He narrated a case in which the symptoms all pointed to a dilated stomach from cicatricial contraction and stenosis of the pyloris. On operation he found the stomach enormously dilated, but with no cicatricial stenosis at the pyloris. There were, however, many adhesions, especially in the neighborhood of the gall bladder, in which viscus he found a gall-stone. This was removed, the adhesions separated, and the patient recovered, with complete relief to the gastric symptoms. It was to be noted that the patient had no symptoms pointing to the presence of gall-stones. Another case had presented the symptoms of acute intestinal obstruction pointing to the lower part of the small intestine. On operation a gall-stone, the size of a walnut, was found twenty inches above the ilio-cæcal valve.

Dr. Senn believes that stones of this size always make their entrance into the intestine by perforation of the gall-bladder and local peritonitis, rather than through the normal biliary passages. He then narrated four cases of desemoid tumor of the abdominal wall, upon which he had operated during the past two years. These tumors originate from the mesoblast, and arise from the sheath of some one of the abdominal muscles. They resemble a fibroma in structure, with some of the characteristics of sarcoma or, at least, a semi-tendency to malignancy. The four tumors were all in child-bearing women, and were perhaps due to trauma, such as the laceration of the sheath of one of the abdominal muscles. They grow faster than the ordinary fibroma, are less distinctly separated at their margins from the surrounding tissues, and internally are often attached to the peritoneum, necessitating an intra-peritoneal operation. The gap in the peritoneum in such cases is closed by making use of the omentum. Diagnosis between intra-mural and intra-abdominal tumors is often very difficult.

A specimen tumor was shown, and a drawing of its microscopic appearance.

Intestinal Lesions in Abdominal and Pelvic Surgery.—Dr. Joseph Price, of Philadelphia, said that it was not his purpose to consider in detail all of every part of abdominal and pelvic surgery so far as their manifold relations are concerned, but only to present the leading features of the part these intestinal lesions play in making the pathology of these complaints complex, and afterward to consider the best way of dealing with them for the good of the patient and the comfort of the surgeon. Aside from the conditions brought about by purely pathological processes, past operative complications, due for the most part to hasty, ill-advised work, or unfinished operations, are at the bottom of a deal of surgical complications that would not otherwise exist. Such operations are the worst that surgery has to deal with, because they involve both old and new inflammations together with the effacement of anatomical landmarks that would otherwise exist. In the same category may be placed complications due to failure to drain and the use of irritating solutions. If we do not drain, the product is likely to go on to organization, or use fluids that encourage inflammatory peritoneal adhesions, it is evident that we are at once on both horns of the dilemma. Meddlesome interference with what would otherwise be natural drainage, by the introduction of quantities of gauze into the pelvis, must of necessity produce adhesions. The less the peritoneum is finally meddled with after the completion of an operation, so much surer is the absence of damaging adhesions. In separating parts and organs joined by adhesions the finger-tips must be used instead of the knife. The complication arising by getting rid of adhesions is hemorrhage. This must not be controlled by ligatures except exceptionally, but by packing and by flushing of the bleeding cavities with very hot water. In all suppurative and inflammatory abdominal and pelvic disease the line of treatment should be as follows: First, remove the diseased organs, then carefully flush the parts free from *débris*, and lastly drain carefully.

The Comparative Merits of Inguinal and Lumbar Colotomy.—Dr. J. Mathews said few, if any, surgeons of this country longer performed lumbar colotomy, preferring the inguinal operation, holding that the first operation had become practically obsolete. The speaker, however, did not consider the inguinal operation to be easier or safer, since the inguinal operation is intra-peritoneal, while the lumbar is extra-peritoneal.

The Significance of a Hernial Sac.—Dr. E. H. Gregory, of St. Louis, said it is of the greatest importance to diagnosticate a hernia before a sac is formed; when a sac has been once formed the patient is liable to any or all of the calamities, such as incarceration or strangulation. Palliative treatment consists in the permanent evacuation of the sac; the radical cure consists of ablation of the sac. The early diagnosis of hernia, and the prevention of the formation of a sac, seems to be the only hope of a perfect result.

The Treatment of Injuries of the Abdomen not Requiring Surgical Operation.—Dr. J. Schneck, of Mt. Carmel, Ill., said that injuries received above the umbilicus are of a much more serious nature than those below that point. This appears to be because the organs above the umbilicus are of much more vital importance than those in the lower portion of the abdomen. One of the most important effects to be aimed at in the way of treatment is to restore innervation. This is best done by the external and internal administration of heat. The internal administration of stimulants is of little or no use, but hot water is always of use, even if vomited, and the injection of hot water is always of use.

Emergency Work in Abdominal Surgery.—In the absence of Dr. Mordecai Price, of Philadelphia, Dr Link, of Terre Haute, urged the importance of immediately following up of any wound in the abdomen, and the sewing up of any wound in the intestine by an ordinary sewing-needle, and such silk and thread that may be at hand, without waiting for a surgeon or the ideally perfect materials for such an operation.

Bassini's Method for the Cure of Inguinal Hernia Applied to a Case Complicated by Undescended Testicle.—Dr. Samuel E. Millikin, of New York, reported the case of a patient, aged eighteen, a machinist, who had been under careful observation for more than a year, with the hope of straining the hernia, at the same time allowing the testis to descend. The truss was worn day and night with but little improvement in the condition, and it was decided to perform the radical operation after the method of Bassini (a description of which will soon appear in the Record), at the same time attempt to anchor the testicle in the scrotum. The case illustrated well the fact that, although the testis and hernia had escaped into the internal rings when the patient was etherized, the sac had not been reduced. When the tendon of the external oblique muscle had been slit up after the above method, the testis was easily reproduced by making traction on the vas deferens, a loop of which remained in the canal firmly adherent to the tunica vaginalis. The sac being congenital, it was necessary to cut it off one inch above the testes and reform the tunica vaginalis. Three catgut sutures were passed through this newly formed tunica and the bottom of the scrotum, simultaneously, for fixation. The inguinal canal being reconstructed, the wound was dressed as a single herniotony.

Hernia, Operable and Inoperable.—Dr. Thomas H. Manley, of New York, reviewed the literature of the subject, and in epitomizing the subject and considering the question of the treatment of hernia in a general way, said: 1. That inasmuch as no operative scheme yet devised will always effectually remove the causes of every species of hernia, in consequence of this a permanent cure is out of the question in certain cases. 2. The radical cure of hernia may be regarded as one of the most satisfactory operations of surgery. The fact that the disease often relapses constitutes no valid objection against surgical intervention, for this is commonly the case in the majority of operations performed on the human body. 3. A radical operation for a non-strangulated hernia which gives no serious inconvenience is not a justifiable procedure, and should not be encouraged unless there are pressing reasons for it. 4. Hernial operations should not be performed in the extremities of age. 5. Unless there are especially contra-indicating factors in given cases, inguinal hernia in women should always be treated by a radical open operation. 6. As a rule, all operations on reducible unincarcerated hernia are radically curative, though the disease commonly relapses. 7. Every operation for strangulated inguinal hernia should always include such additional steps as will effect thereafter a complete obliteration of the inguinal canal. 8. Very large old herniæ in any of the abdominal regions are not operable, except in case of strangulation.

A Few Points on the Management of Strangulated Hernia.—Dr. W. B. Degarmo, of New York, said that the death-rate from strangulated hernia is far in excess of what it should be, and this on account of the faith placed in certain internal remedies, as well as owing to the exaggerated ideas as to the difficulties of operating for its relief. He believes that the physician who waits to test the merits of the various non-surgical methods is wasting valuable time, assuming grave responsibility, and probably sacrificing the patient's life. A warning is sounded regarding those cases where local pain is absent, and another is given respecting those where all symptoms have been masked by the use of the hypodermic syringe. It is believed that many lives have been sacrificed as a result of its use. Shock or collapse is considered a symptom of the gravest importance, indicating the necessity of very prompt surgical relief. Medical treatment is believed, on the whole, to be unreliable, and in many instances injurious; as a means of reducing hernia no reliance whatever should be placed in it. The causative action of mus-

cular spasm is not believed in; among external applications only one is commended, and that is (after Frinkelstein), of pouring a small amount of sulphuric ether over the tumor every few minutes, the parts being exposed to the atmosphere to favor rapid evaporation. This is recommended only in the early stages, before the vitality of the parts has been impaired. "Taxis," as ordinarily performed, is condemned, and a method of traction and compression is described, its object being to lengthen out the neck of the tumor, relieving by compression the engorged blood-vessels and imprisoned fluids and gases. Anæsthetics purely as a means of reducing hernia is not commended, although careful manipulation, under their effect, should always be used before proceeding to the operation; aspiration is not looked upon with favor, except in some very rare cases. Regarding operations, it is believed that the Emly operation is one of the most simple in surgery, and that it should always be done early. Waiting for fæcal vomiting belongs to the (surgical) dark ages. It is believed always safer to open the sac and examine contents. Numerous aseptic silk ligatures are recommended in amputating masses of omentum, instead of tying off with one ligature of catgut. If the bowel is of dark chocolate color, but not necrotic, the application of hot compresses after cutting the constriction is advised. In gangrenous gut temporary artificial anus is believed to be the safer method for the patient. The use of methods for favoring permanent cure to follow operations for relief are strongly commended The author has used silk exclusively in all hernia operations for four years, and since he has sterilized and prepared it himself has had no trouble about its coming out of the deep muscular tissues.

The Management of Gangrenous Hernia.—Dr. Joseph Ransohoff, of Cincinnati, cited the statistics of strangulated hernia during the past twenty years. Of these only fourteen per cent. were found gangrenous. Four cases were reported in detail. In two, operation was made by returning the suspicious area to the abdomen; these died. The other two were operated upon by dividing the constricting band, excision of the gangrenous portion, and returning of the healthy part to the peritoneal cavity; these cases recovered, and the writer discussed at length the steps of the operation and the logic by which this treatment might be expected to lead to satisfactory results.

Discussion of Hernia.—Dr. Marcy, of Boston, after discussing the subject at considerable length, summed up, as essentials for operation, the following: 1, asepsis; 2, resection of the sac; 3, restoration of the obliquity of the canal in inguinal hernia in the male; 4, closure of the wound by means of buried tendon sutures; 5, coaptation of the skin by a blind buried suture, and sealing with iodoform collodion, re-enforced by a few fibres of cotton without drainage.

Discussion on Abdominal Surgery.—Dr. B. A. Watson, of Jersey City, said that the essential in all abdominal operations was asepsis. If we knew the condition of the peritoneal cavity as to asepsis, we should know when to operate and when not to operate. Not knowing this, he would be inclined to wait a little and be guided by the symptoms presenting, watching carefully and being ready to operate at any hour. He strongly deprecated the teachings of Dr. Link, that the family physician and the country doctor should operate in all cases at once without waiting for the arrival of the surgeon, holding that no one not familiar with the details of antiseptic work should attempt an abdominal operation, or, indeed, any operation whatever.

The following officers were elected to serve for the ensuing year: *Chairman*, Dr. James T. Jelks, of Hot Springs, Ark.; *Vice-Chairman*, Dr. E. T. Tappey, of Detroit, Mich.; *Secretary*, Dr. Liston Montgomery, of Chicago, Ill.

The Grady Hospital at Atlanta, Ga., has been completed and formally presented to the city.

AMERICAN SURGICAL ASSOCIATION.

Annual Meeting, held in Boston May 31, June 1 and 2, 1892.

First Day, Tuesday, May 31st—Morning Session.

Address of the President.—The Association was called to order by the President, Dr. P. S. Conner, of Cincinnati, who delivered the Annual Address as follows:

Fellows of the American Surgical Association: After a series of meetings at the national capital, it is fitting that our first journeying should bring us to a city with which is associated so much that is good and great in the history of our country—political, literary, scientific, and professional. Here, as a part of the University that, like Salernum of old, is *mater et caput* of the schools, was established the second medical school in the Western hemisphere, where for more than a century scientific medicine has been well and thoroughly taught. The Massachusetts General Hospital and the City Hospital have been the theatres of much work that has strongly affected the practice of our art the world over, and one of them will ever be remembered as the place in which "the problem of surgical anæsthesia was definitely solved." Their surgeons, learned, skilful, progressive, and inventive, by labors and teachings have honored themselves and the profession of which they have been so distinguished members. Not in America only, but everywhere, the profession has held and now holds in high esteem the medicine and surgery of Boston.

The active life of the Surgical Association, that began with the meeting in Philadelphia, embraces a ten-year period than which no other in professional history has been more strongly characterized by extent and accuracy of investigation, by scientific, judicious experimentation, by the discovery of important facts, by improvements in the technique of old operations, and by the introduction and general adoption of new procedures. In the study of the causes of disease, many master minds have been at work, and more positive knowledge has been gained than in all time before, so that in the bacteriological laboratories a new pathology has been worked out, in large measure revolutionary of both opinion and practice. Speculation and theory have given place to experimentation and fact, and the disease-producing influence of airs, of earths, of waters, have been found to lie in organisms that have been seized upon, separated, classified, and tested.

We can scarcely realize that it was only in 1882 that the startling announcement was made that tuberculosis was consequent upon the presence and action of a definite micro-organism, that could be isolated, cultivated, and inoculated; and that so short a time ago, the doubters were many, more, indeed, than the believers. In this single decade just passed, the fact has become universally acknowledged, the sceptics are now but professional curiosities; a new literature has been written, even a new language created in which strumous (except as a synonym of tuberculous) has no more place than phlogiston.

The long-known chronic affections of bones, of joints, of glands, of skin, have been shown to be in great measure the result of the presence and action of a bacillus, that everywhere and under all circumstances moves in one and the same way, and that a destructive one, though antagonized at every step by the healthy tissues (not seldom successfully), and subject more or less completely to the power of our art, directed to the procuring of the destruction or encapsulation of the germ, the removal of the infected tissues, or the taking away of the affected part. We can understand now why rest is of so much importance, why excision or erasion may be followed, as it so often is, by non-recurrence; why, on the other hand, in spite of, or even because of, operative interference, parts near or remote become secondarily infected.

The most important work, as it seems to me, that has

been done in connection with surgical tuberculosis, is that which has had for its object the finding out and properly applying a therapeutic agent which will destroy the organism and secure its expulsion from the body, or secure such condensation of non-affected tissue about it as shall form a wall around, and by encapsulation render it harmless. Far better will it be to administer generally or locally a remedy that will remove the bacillus or make it innocuous, than to do the most brilliant operation followed by the most rapid healing and recovery in large measure of functional integrity. The end is far from having been reached, but a long step in advance has been made, and the reviewer of the work of another ten years may find the result secured, and a non-operative, truly murative treatment in use. It is certainly to be hoped, though, that scientific medicine will not again have to pass through such an experience as that of a couple of years ago, the history of which will always be of much interest to the students of psychology and of mental epidemics.

Of the three wound complications which from the earliest times have been the bane of surgery, septic infection, erysipelas, and tetanus, the cause of only the first had been determined a decade ago, that of each is now known, and known because of the application to the tissues and fluids of those affected by them of the same methods of bacteriological investigation that had revealed the existence and life history of the pyogenic cocci. In erysipelas have been satisfied the three requirements of proof of bacterial origin, isolation, cultivation, and inoculation into the human subject, with resulting development of the original disease. Not a few of the long-time perplexing questions connected with tetanus have found answer in the discovered identity of its causative organism with the earth bacillus and in the anærobic nature of it. In every case that has come under my observation, so far as I can recall, except those associated with toy-pistol wounds, I am able to trace either direct contact with the naked ground, or probable, almost unavoidable, contamination of the wound with dust and dirt. In the toy-pistol wounds of the hands there is that exclusion of air and retention of fluid that are most favorable to the growth and activity of secretion of an organism that flourishes in the absence of oxygen, an organism that at the time of injury or later was located doubtless upon the dirty hand. Knowledge of the habits of the bacillus is sufficient of itself to indicate the treatment to be pursued, that tetanus may not supervene, to wit, thorough opening up and free drainage of the wound. Further, not only has the causative organism been found, but also it has been shown that there may be developed from it an antidotal chemical agent, the injection of which can produce immunity or act remedially upon a tetanic patient.

It is in the treatment of the diseases and injuries of the viscera and their envelopes that the greatest advances in our art have been made in these later years. Numerous and carefully conducted experiments upon animals, and operative procedures upon man, new, bold, and highly successful, have again and again been reported, and in the work that has been done our own Fellows have had no minor part.

The abdominal cavity, that for so long a time was an almost sacred territory, not to be invaded except under peculiar circumstances and for the relief of a very few morbid conditions, has, because of the secured protection against sepsis, become one of the more common fields of operation, done on account of wounds, of tumors, of obstructions, and of infective inflammation. Such operations not seldom have been, it may be believed, ill-advised, ill-timed, unnecessary, and harmful, entered upon by inexperienced men, whose eagerness to cut has found explanation in the fact that, in simple abdominal section few operative difficulties are usually met with and no dangerous hemorrhage is to be expected, the arresting of which might test the knowledge and skill of the operator.

Penetrating and perforating wounds of the hollow and solid viscera are no longer treated solely by opium and ice, with a resulting fatality truly appalling, but by section of the wall, suture of the wounds, ligation of the bleeding vessels, and antiseptic plugging, if necessary, of openings in the solid organs. The mortality-rate is still unfortunately very high; how high cannot be definitely stated, since the number of reported cases is yet limited and includes without doubt an undue proportion of successful results. Not a few of the deaths, it cannot be doubted, have been due to the delay, the incompleteness, and the imperfection of the operation, but many must be credited to the damage primarily done. Made by bullets of other than the smallest calibre, a pistol-wound of the stomach, of the intestines, of the mesentery, or of the liver, is likely to prove mortal from shock or hemorrhage even though treated properly and skilfully; and is almost absolutely certain to do so if fecal extravasation has occurred and septic inflammation has set in. It cannot be questioned but that wounds made by very small balls may be, and have been, recovered from without operative interference, and there is good reason for believing that in the absence of symptoms of active hemorrhage, such wounds will do as well or better without as with laparotomy; an operation, however improved its technique, is still an addition to the risk of the case. It is as unwise as it is untrue to declare that there are no dangers attaching to incision of the abdominal walls and exploration of the intestinal tract. But when it is a bullet of large size that has entered the cavity, the safety of the patient almost certainly lies, if anywhere, in speedy, thorough operation. It is hard to understand such statistics as those of Reclus, in which it would appear that, while without operation only thirty-five per cent. died, with operation the mortality-rate was from seventy-three per cent. to eighty-six per cent. That in three out of four, or six out of seven, patients thus wounded the result was a fatal one, may be believed, but that it should be so in only one out of four expectantly treated, is, to say the least, very remarkable. Not the smallest of difficulties often associated with these wounds, is the determination of the occurrence of penetration, which at times can only be through opening up and following down of the parietal wound. Inflation of the bowel with hydrogen gas, the earlier experiments with which were so brilliant and so captivating, will not always give the desired information, and may be positively detrimental to the best interests of the patient, as it certainly has been in certain cases already put on record.

The septic inflammations about the head of the colon, originating so generally in the appendix (which some would regard as an "intestinal tonsil," but may well be looked upon as a useless survival of a once important organ), have in the period under consideration been brought within the province of the surgeon, not as before at a late day, when the resulting abscess has fortunately come well forward toward the surface, but at an early stage, when by evacuation of the fluid with or without removal of the appendix, relief may be afforded and the patient be protected against the lethal effects of perforative peritonitis or perinephritic suppuration. The cases of acute disturbance in the region of the cæcum due to an over-loaded bowel or to the catarrhal inflammation, will find relief in the future as in the past in the therapeutic measures of the physician; but suppurative gangrene producing appendicitis, it has been proven, and that chiefly by the experience of our American surgeons, can with safety be treated only by the knife. Whether or not it is advisable to remove, during a quiescent stage, the appendix that has been the seat of repeated attacks of inflammation, is a question as yet unsettled.

A very cursory examination of the professional literature, home and foreign, for the past decade, would convince anyone that an immense amount of work, experimental and operative, has been done in the determination of the proper and most advisable methods of

treatment in cases of obstruction, acute and chronic, malignant and non-malignant, located in any part of the tract from the cardiac extremity of the stomach to the lower end of the rectum. Strictures have been dilated, affected areas removed, anastomosis secured, "cut-offs" established, new openings formed, with the result in favorable cases of effecting cure or affording relief. The technique of the older operations has been much improved, modifications have been introduced, and not a few altogether new procedures have been devised, tested, and widely accepted.

Pyloric stenosis, for which ten years ago pylorectomy was all that the surgeon could offer, may now, if of non-malignant character, be relieved by digital divulsion through the open stomach, by curetting, by a pyloroplastic operation, or by gastro-enterostomy; and if due to malignant disease, by the latter operation, in every way to be preferred to excision of the cancerous mass, being speedier and easier of execution, and having a mortality-rate but one-half or perhaps only one-fourth as great. In its performance, as in similar operations upon lower portions of the intestine, much use has been made of the approximation plates, as of decalcified bone, of leather, or of potato, and of cat gut rings and mats; but at the present time there is certainly a strong and growing feeling that their employment is not only not necessary, but rather an injury than a benefit to the patient. It may well be questioned if, after all, viewing the subject in its widest aspect, operations for cancer of the stomach have really been or can be of much service. They certainly have often afforded much temporary relief, and are to be resorted to when suffering is great and starvation is imminent; but on the other hand, the prolongation of life when the operation is recovered from is, with only now and then an exception, but slight; excision has almost never protected from recurrence, the abnormal anastomoses are very likely to speedily become seriously contracted, with resulting loss of the benefit primarily secured, and the necessitating disease must go on increasing, though it may be more slowly than before. In not a few of the reported cases the condition of the patients at the time of operation was fairly good, the suffering was slight, and the general strength but little impaired, yet as the direct result of the surgical interference life was cut short. If we balance these cases against those in which a few weeks or months were gained by excision or anastomosis, it is very questionable if we can find in the result of operation any material addition to the sum total of life.

Malignant disease located in the rectum, too low to be removed through an anterior abdominal incision, and too high to be thoroughly extirpated through a perineal one, may be reached from behind, after resection of the coccyx, with or without, as necessity may require, that of the lower portion of the sacrum. This new operation, neither specially difficult nor dangerous, may be done in place of a colotomy, lumbar or inguinal, the latter being to-day more generally preferred. The same objection to such radical treatment as compared with palliative, viz., increase of risk without compensating probability of cure, holds good here as at the pylorus, although in less degree.

In no other part of intestinal surgery has more been done in thought, in experiment, and practice, than in that dealing with excisions of the bowel in continuity, rendered necessary on account of wounds, growths, or gangrene. As the technique of the operations has been improved, the time of performance has been lessened, the risk to life diminished, and the range of applicability increased. It is still undetermined whether end to end or lateral anastomosis is to be preferred, of how much value bone plates, or rings, or other like aids really are, to the patient at least; how far omental grafts may be required, or how much additional security they afford.

The solid organs have again and again been brought under surgical treatment on account of wounds, of growths, and of tubercular, parasitic, and suppurative diseases.

The kidney, spleen, and even the pancreas have been removed entire, the liver in part. The gall-bladder has been opened and its contents removed (stones, bile, pus) and later sutured and left in place, or stitched to the abdominal wall, or cut away altogether. Pancreatic cysts have been at times extirpated, at times drained. These operations have yearly been more frequently performed for more varied causes, by steadily improving methods and with a marked diminution in the resulting fatality,

Special notice cannot be taken of the new and improved operations upon the uterus and its appendages, which have had for their object the relief of the distressing and grave conditions, and as their results, preservation of life and restoration to health in a large and steadily increasing proportion of the cases treated.

Of the work done upon the bladder much might well be said; but only a passing reference to the high esteem in which, so justly, the supra-pubic section is now held; to the greatly improved and more successful treatment of tumors, and to the established position that, in the period under consideration, litholapaxy has taken as the most generally applicable method of dealing with stone, even in young children, for the relief of whom ten years ago lithotomy was everywhere regarded as the only operation to be ordinarily thought of.

Though there have been many operations of very considerable extent upon the thoracic wall to secure closure of an empyemic cavity and for the extirpation of tumors, in intra-thoracic surgery but little has been done, and that almost entirely in the evacuation of lung abscesses and the removal of hydatid cysts; the result in the latter class of cases has been remarkably successful. Pneumonotomy for tubercular abscess, according to the report made to the French Congress of Tuberculosis last year, had relieved in about fifty per cent. of the cases and cured about one-fourth as many, but the number of patients thus far treated has been so small that the figures are of little importance in the consideration of the advisability or otherwise of active interference. It certainly stands to reason that the opening up and draining of the pulmonary tubercular abscess will not be likely to afford other than temporary relief, such pus collection being commonly not solitary, but one of a number in an extensively diseased organ. In the removal of deeply located foreign bodies and tumors other than those connected with the wall, almost nothing has been attempted, and there are difficulties, anatomical and physiological, in the way of such operations, which if in any given case not insuperable, will probably always tend to make prudent surgeons cautious about entering upon one of them.

Pneumonotomy, experimentally shown to be readily done and attended with no great amount of danger, will doubtless in the future have a place in the treatment of lung injuries, in which already it has been a few times employed; according to one report in fifteen cases, with a death-rate of less than fifteen per cent. That it will ever be an accepted method of treatment for tuberculous lung, may well be questioned.

(To be continued.)

Salol: its Danger and Antidote.— Dr. Chlapowski (*Therap. Monatsh.*, 1891) relates an instance in which, to use Ewald's method of testing the motor power of the stomach, fifteen grains of salol were given to a woman with indigestion. Restlessness, followed by unconsciousness, dilated pupils, irregular pulse, and constant vomiting, dark urine, and death, twelve hours later, was the result. Hemorrhagic gastritis and enteritis were found. In all cases where large doses are employed the state of the kidneys should be looked into, and if symptoms of poisoning come on sulphates should be administered, preferably the sulphate of sodium.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE ADJOURNED DISCUSSION ON RENAL DROPSY—FURTHER REPORT OF THE VACCINATION COMMISSIONERS—THE NEW UNIVERSITY FOR LONDON COMMITTEE—THE LONDON DENTAL HOSPITALS—DISAPPEARANCE OF INFLUENZA.

LONDON, May 14, 1892.

THE discussion on "Renal Dropsy" at the Medical and Chirurgical Society was resumed this week and brought to a conclusion. Dr. Douglas Powell opened the adjourned debate. He said he agreed with the view that dropsy occurring late in chronic renal disease was due to the cardiac failure rather than to the renal disorganization. In acute tubal nephritis dropsy generally appeared early and diminished as the pulse-tension increased. Occasionally there was suppression of urine at an early stage without dropsy, and in such cases there was nearly always uncontrollable vomiting or diarrhœa, which probably compensated for the want of excretion of urine; if the patient survived this condition, then dropsy set in. Dr. Mahomed had asserted that high tension of the pulse preceded the kidney change in post-scarlatinal nephritis, but Dr. Powell said he doubted whether this increased tension was more than occurred at the onset of other acute diseases. He thought the high tension which occurred when the disease had passed beyond the acute stage was compensatory to insure renal secretion from a damaged kidney. Osmosis was, at any rate, a factor in the production of dropsy in renal disease.

Dr. Broadbent said he agreed generally with Dr. Dickinson's conclusions. There was probably a similar causation for cardiac and renal dropsy. He had long thought that the obstruction to the peripheral circulation had its seat in the capillaries—the sclerosis of the arterioles being subsequent and protective to the capillary net-work. The late dropsy of long-standing chronic Bright's disease was undoubtedly due to cardiac failure.

Dr. Sansom said he did not think the phenomena of cardiac and renal dropsy could be explained entirely by dynamic forces. He would substitute "prolonged arterial tension" for the term "high arterial tension." There were two factors in determining the tension, viz., the contraction of the arterial walls and the strength of the heart's action. In chronic renal disease the arterial tension was not a constant quantity. Should some intercurrent fever set in, the high tension disappeared, but there was no alteration in the dropsy. The seat of the obstruction which caused the dropsy was undoubtedly in the capillaries. Dr. Sansom said he believed that the important factor in the production of the dropsy was the presence of some lymph product. Wooldridge had shown that by injecting some lymph product into the circulation dropsical transudation could be induced.

Dr. Haig maintained that it was the presence of uric acid in the blood which caused the contraction of the capillaries and arterioles, and so prevented the escape of water from the skin, lungs, kidneys, etc.

Dr. Lazarus-Barlow urged that the causation of dropsy was twofold in renal disease, viz.: 1, Deleterious substances in the blood damaging the capillary walls; and 2, diminished pressure in the capillaries, due to the arteriole contraction. The difference of liability to erysipelas pointed, he thought, to a distinction between cardiac and renal dropsy.

Dr. Dickinson then replied. He referred to the marked way in which difference of pressure on the two sides of a membrane affected its osmotic power. He felt sure the primary obstruction was in the capillaries, and it was reasonable to suppose that the muscular and fibroid thickenings of the arterioles were both due to the changes in the capillaries. Osmosis alone was not sufficient to account for renal dropsy. The difference in composition of the fluid in renal dropsy and in inflammatory exudations disproved that the former was simply inflammatory in nature. Dropsy disappeared after the establishment of cardiac hypertrophy owing to three causes: 1, The increased flow of urine; 2, the increased suction power of the heart; and 3, the contraction of the arterioles. He thought Dr. Powell ascribed too much power to osmosis.

The Royal Commissioners on Vaccination have issued a further interim report, in which they recommend the abolition of repeated penalties in respect of the non-vaccination of the same child.

Great offence has been given to a considerable section of the graduates of the University of London by the action of the Government in regard to the constitution of the new commission. It is maintained that among the commissioners there is not one who can be said to really represent the existing university.

London has two dental hospitals. Both are contemplating a removal to fresh premises. The National Dental Hospital is located in Great Portland Street, and the managers are now erecting larger premises on a fresh site in the same street. The older hospital, in Leicester Square (Dental Hospital of London), is also about to be moved, but the site has not yet been decided upon.

No death from influenza was registered in London last week, and the disease has practically now disappeared.

MEDICAL LEGISLATION IN NEW YORK.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: The record of the last Legislature, on medical affairs, was mostly of a negative nature. The most important bill was that known as "The Students' Bill," introduced by Senator O'Connor and Assemblyman Patchin. It amended Section 11 of Chapter 507 of the Laws of 1890, entitled "An Act to Establish Boards of Medical Examiners of the State of New York for the Examination and Licensing of Practitioners of Medicine and Surgery; and to further Regulate the Practice of Medicine and Surgery," as amended by Chapter 311 of the Laws of 1891, so that the act should not apply to any student who duly matriculated in a legally incorporated medical college of the State of New York before the first day of December, 1890; provided that such student, within three months after the enactment of this amendment, shall file with the Secretary of the Board of Regents of the University of the State of New York a certificate setting forth the fact of such matriculation, verified by the applicant and signed by the secretary of the faculty of the college in which he matriculated. This bill passed the Senate, but not the Assembly. It was antagonized by all the medical profession of the State. There is a rumor that the students will introduce a bill of a similar nature next year; and, if they fail in passing it, that they will try to cut down the fee paid by the students from $25 to $10. The fee in Germany is now $51.50.

Another very important bill which failed to reach the Governor was introduced by Senator McClelland. It granted a charter to the Bayard Homœopathic College Hospital and Dispensary. This bill was also fought on the ground that the charter would allow the college to give instruction according to the Bayard theory only, and that students could pass an examination after a course of but two years. Another peculiar feature was that the charter granted no property rights to the college.

A third bill, known as "The Stiff Bill," was vetoed by the Governor, although it passed both houses by a heavy vote, Speaker Bush taking the floor in favor of it on its passage through the Assembly. The bill allowed the same privileges, as to the securing of corpses, to medical schools that are now enjoyed by medical colleges. This bill has a curious history. It passed the Assembly in 1890, but it was not reached in the Senate at the hour of

adjournment. In 1891 it reached the Governor, but he found so much fault with it that it came back to the Legislature only to be killed in the deadlock. The Governor's veto of this year was on the ground that the bill was defective in construction, and that it was drafted in apparent ignorance of Chapter 280 of the Laws of 1887, and therefore omitted the important amendments contained in that chapter.

The new amendments to the Penal Code, from the Commissioners on Statutory Revision, contain certain important provisions in regard to apothecaries, including medical prescriptions and the selling of poison without labels.

The act for the prevention of blindness, Chapter 41 of the Laws of 1890, was repealed by Chapter 325 of the Laws of 1892.

A very important bill, introduced by Senator Cantor, became a law, Chapter 528. It codifies the laws regulating the practice of dentistry, and punishes forgeries and frauds in medical and dental diplomas. The provisions are that only persons over twenty-one years of age, who have graduated at an institution approved by the Dental Society, have registered at the office of the county clerk, stating their legal authority to practise in this State, and presenting a certificate from a member of the State Board of Censors appointed by the State Dental Society, shall practise dentistry. A fee of fifty cents shall be paid to the clerk. The Censors shall consist of eight, from each of the district societies, to serve four years. Every person now practising shall file within three months a statement of qualifications. Every student shall pay a fee of $5 to the secretary of the State societies for a certificate. Before filing a certificate every applicant for a Censors' certificate shall pay on application $10, and every applicant for examination by the Censors shall pay to the Secretary $30. No fee shall be returned, but if the applicant fails he may be examined again without extra charge.

A new law provides that the Western Dispensary of the City of New York, heretofore incorporated pursuant to the provisions of "An Act for the Incorporation of Benevolent, Charitable, Scientific, and Missionary Societies," passed April 12, 1848, and the acts supplementary thereto and amendatory thereof, is hereby consolidated with and merged in the Hahnemann Hospital of the City of New York, heretofore incorporated pursuant to the provisions of said act, passed April 12, 1848, and the acts supplementary thereto and amendatory thereof, as modified and extended by Chapter 64 of the Laws of 1875, entitled "An Act Concerning the Hahnemann Hospital of the City and County of New York," passed March 20, 1875. The charter of the West Side German Dispensary in the City of New York was amended so that the number of trustees should not exceed thirteen at any time.

Another law provides that the members of the Medical College Laboratory of the City of New York, a corporation created by Chapter 125 of the Laws of 1883, may at any time assign and transfer to said corporation their individual shares or interest in the property of such corporation upon such trusts for educational and scientific purposes, and subject to such provisions and conditions as said members and such corporation shall agree upon, with power to said corporation for the purposes aforesaid, at any time thereafter, to enter into agreement with the University of the City of New York for the use of such property, and with further power at any time, in its discretion, to convey and transfer by deed or gift to said University of the City of New York, any or all of such property; but the rights of any creditor of said Medical College Laboratory of the City of New York shall not be thereby impaired.

An amendment to the charter of the New York Dispensary was made, so that the members of the corporation shall be those persons who are now members of the same for the periods for which they are now entitled to membership in said corporation, and such other persons, contributors to the said dispensary, as shall be elected to membership in such corporation by said board of trustees from time to time. The board of trustees may elect such members for life or for lesser periods, and may grade the amount of contributions to be made by such members accordingly, and may make such rules and regulations in reference to such membership and the payment of such contributions as to the board may seem expedient.

The German Policlinic, in New York City, was exempted from taxation.

The Governor vetoed an item of $5,000 in the supply bill for books, serials, binding, and other necessary expenses of maintaining the State Medical Library, pursuant to Chapter 377 of the Laws of 1891, on the ground that the appropriation was not deemed advisable at the present time.

He also vetoed an item in the same bill, for the three State Boards of Medical Examiners, for travelling expenses in attending necessary meetings, payable on vouchers approved by the Comptroller, $1,200, or so much thereof as may be necessary to meet the deficiency caused in the provision for such expenses by Chapter 311 of the Laws of 1891, exempting medical students from the payment of examination fees, on the ground that "the intention of the law creating State Boards of Medical Examiners was not to involve the State in any expense. The expenses of the Medical Examiners were to be paid out of the examination fees, and the Examiners were to be the beneficiaries of all surplus receipts. While the amendatory Act of 1891, Chapter 311, may have diminished the amount of fees received, I am not convinced that any temporary deficiency should be paid out of State revenues."

Still another veto was that of an Amendment to the Veterinary and Surgery Laws, extending the time of registering till January 1, 1893.

If Assemblyman Stein's "Anti-spy" Bill had become a law, no illegal practitioner of medicine could have been apprehended unless he had been actually employed by the informer; and, in that case, the informer himself would have been arrested and made as guilty as the illegal practitioner.

A large number of bills failed to reach the Governor. Some of them had merit and some of them did not. Among them were the following:

Senator Parker: Providing for the appointment by the Regents of a board of five members to serve three years, and to act as a Board of Examiners of those wishing to engage in the business of undertaking, as the Board of Medical Examiners now acts in regard to those wishing to engage in the practice of medicine. Appointments shall be made by the Regents from a list of ten candidates furnished by the State Undertakers' Association. The object of this bill was to discover whether an undertaker is properly qualified to do embalming. Probably it will be introduced next year, with certain amendments.

Senator McCarren: Declaring that it shall not be lawful for any corporation organized under the Laws of this State, and having the care, maintenance, or custody of children or invalids, to make use of the services of any physician who is not a citizen of the United States.

Assemblyman Malone: Amending Section 834 of the Code of Civil Procedure so that, in cases where persons are suffering from personal injuries, no physician, medical student, hospital nurse, or any other person shall, except for the purpose of medical treatment, examine or obtain from any person or persons injured a statement of his or her injury, or of the accident, or an account of how such accident happened, while such person is under medical or surgical treatment for the injuries received; and no information obtained by physicians, medical students, hospital nurses, or other persons from a person injured while suffering from such injuries, or while subject to medical or surgical treatment, shall be disclosed by such physician, medical student, hospital nurse, or other person, to anyone for any purpose; and such communication shall be considered as privileged, and shall not be used or referred to upon the trial in any court of justice in this State. It

is believed that this bill was to prevent adjusters from settling up accidents on the spot.

Senator Roesch: Providing that in actions for damage from personal injury the testimony of a physician may be taken before a referee, or the physician may be summoned by the judge.

Senator Roesch: Providing that physicians and surgeons in attendance on hospitals shall be given forty-eight hours' notice in cases of subpœna to appear in cases of suit for personal injury. This bill was approved by Commodore Elbridge T. Gerry.

Assemblyman Riley: Amending the State Board of Pharmacy Act of 1884 so that any person who at the time of the organization of said Board, as provided by this act, was entitled under the provisions thereof to be licensed as a pharmacist, but who failed within said ninety days so to apply to said Board, may upon application of not less than eight days' notice served upon the Secretary of said Board, apply to the Supreme Court, at a special term thereof held in the district where such applicant resides, for an order directing said Board to issue such license; and said court shall have power to grant the same on proof of good cause shown for the neglect to apply for said license in due time, and the said Board shall issue such license on receipt of a certified copy of said order served upon the Secretary of said Board.

Senator McCarren: Amending the law for the sale of drugs and poisons in Kings County, so that the Board of Pharmacy of Kings County shall consist of five members, to be elected by the Kings County Pharmaceutical Society, from its members, at a special meeting to be called for that purpose within two weeks after the passage of this act, and one of which number so elected shall also be elected by the said Society to act as secretary of the said Board. As the law now stands it provides that the Board of Pharmacy of the County of Kings shall consist of five members, two of whom shall be pharmacists qualified for registration as aforesaid, to be elected by the Kings County Pharmaceutical Society, at a special meeting to be called for the purpose within two weeks after the passage of this act; two practitioners of medicine to be elected by the Medical Society of the County of Kings, at its next stated meeting after the passage of this act; and a pharmacist, who shall also be a secretary of the Board, to be elected by the joint ballot of the members elected as herein provided for.

Senator Hagan: Providing for a Health Department Pension Fund in the city of New York. This bill was urged by several prominent physicians of that city. It provided that the Board of Health of the city shall be a Board of Trustees of the Health Department Pension Fund, authorized and provided for in the bill. Such trustees shall have charge of and administer the fund, and they shall report in detail to the Board of Aldermen, in January of every year, the condition of the fund. They shall serve without salary or compensation. The Health Department Pension Fund shall consist of: 1. All moneys paid for searches and transcripts of the records of births, marriages, and deaths, or other papers of said Department of Health. 2. All moneys collected from fines and penalties for violations of the sanitary code or health laws in the city of New York. 3. Such sum or amount of money as may be appropriated therefor by the Board of Estimate and Apportionment in the city of New York, in its discretion, from moneys received from excise or theatrical licenses. The said moneys shall be paid to the Board of Health, and received by said board and applied to the use and purpose of said pension fund. The Board of Trustees of said fund shall have power to grant a pension to any physician employed in the Health Department of the city of New York, or to any employee of the disinfecting corps of said department, and to any employee of the hospitals for the cure of contagious and infectious diseases under charge of said Board of Health, who shall, while in the actual performance of his duty as such physician or employee, and by reason of his performance of such duty, and without any fault or misconduct on his part, have become permanently disabled, physically or mentally, so as to be unfitted to perform full duty, a sum not to exceed one-half nor less than one-fourth of his rate of compensation per annum as such physician or employee, as the case may be. Whenever any such physician or employee shall die while in the service of the Board of Health, from disease contracted or injuries sustained by him while in the actual performance of his duty, without any fault or misconduct on his part, leaving a widow, the Board of Trustees of the Pension Fund may pay to the widow of said physician or employee the sum of $300 annually during her life, or so long as she remains a widow; and if there be no widow of any such physician or employee, but there shall be minor children under eighteen surviving him, then said $300 may be paid to said children while under eighteen years of age. No physician or employee of the Board of Health shall be paid a pension on account of physical or mental disability or disease, unless upon the certificate of a board of physicians appointed by the Board of Health, which shall set forth the cause, nature, and extent of the disability, disease, or injury of such physician or employee who may be placed on the pension-roll; and such certificate shall distinctly state whether or not such disability, disease, or injury was incurred or sustained by such physician or employee while in the performance of his duties as such physician or employee of the Board of Health; and such certificate shall in such case be filed with and entered upon the minutes of the Board of Health. Any such physician or employee who has or shall have performed duty as such physician or as such employee in the Department of Health, in the city of New York, for a period of twenty years or upward, upon his own application, or upon a certificate of a board of physicians appointed by the Board of Health certifying that such physician or employee is permanently disabled so as to be unfit for further duty as such physician or employee, may, in the discretion of the Board of Health, by a resolution unanimously adopted by a full board, be retired from service and placed upon the Health Department Pension-roll, and thereupon shall be paid from said Health Department Pension Fund, by the trustees thereof, an annual sum during his lifetime not exceeding one-half the full pay of such physician or employee, as the case may be, of the Health Board of the rank of the physician or employee so retired; provided, however, that no pension granted shall exceed the sum of $1,200 per annum. Pensions of this sort shall be for the natural life of the person receiving the same, and shall not be revoked, repealed, or diminished. In determining the term of service of any such physician or employee, service in former boards of health having jurisdiction in matters of public health in the city of New York, shall be counted and held to be service in the Department of Health in the city of New York. The Board of Health may, in its discretion, order any pension granted, or any part thereof, to cease, except as provided above, but in all such cases the Board of Health shall file with the trustees of the Health Department Pension Fund a written statement of the causes which determined them in ordering any pension to so cease; and nothing in this act or in any other act shall render the granting or payment of such pension obligatory on the Board of Health or upon the trustees of the Health Department Pension Fund, or chargeable as a matter of right upon said fund, except as provided herein before.

The bill which was more ridiculed than any other by the medical profession was introduced by Assemblyman Goldberg. This bill made it a misdemeanor for any but a licensed physician, in lecture courses to medical students or before scientific bodies, to give exhibitions of or to perform hypnotic demonstrations in public, or for any but a licensed physician to hypnotize another. The Legislature did not pass the bill.

ALBANY, May 27, 1892.

THE SANITARY CONDITION OF CHICAGO.

To the Editor of the Medical Record.

Sir: Having resided in Chicago for a time, the writer can venture an opinion as to the sanitary condition of that city.

The city limits have been enormously extended, and an already severely overtaxed water-supply tapped to furnish water to each new addition from time to time. One of the inducements to buy lots is that "they are connected with city water and sewer." Any resident of Chicago who holds or desires to hold an official position is not politically indiscreet enough to offend the "real-estate" men by decrying the sanitary condition of the city.

In case of a fire the water is shut off from large districts for from twelve to seventy-two hours at a time. People in their strait for water rush in search of old wells, which more often than otherwise are under houses or stables, many of which wells have not been used for a long time. This water is used with no precautions against any contaminating properties it may contain.

The street-cleaning service is notably slack. The carcasses of dead animals are allowed to remain where they die an inexcusable length of time.

The ambulance system of the city is more of a rumor than a reality. An ambulance on the streets of Chicago is nearly as much of a curiosity as an elephant. The victim of accident or sickness is bowled along over the rough streets in a police patrol wagon. The by-standers put him down as "a drunk."

The hospitals are inadequate to meet the demands of a city of four hundred thousand inhabitants. Large portions of the city are without hospital advantages, much to the detriment of the sick poor.

In a city of Chicago's size and boasted reputation one would scarce expect to see physicians who enjoy large practices, and who profess to keep up with the times, have the hardihood to stand up before a Medical Society and give utterance to the following remarks: "I have seen cases of typhoid fever in which the bowels were absolutely normal from start to finish. In my opinion it is essentially a nervous disease, and originates in the brain. All ulceration of the bowels (if there ever is any ulceration) (?) is due to perverted secondary nerve action." Another: "We all know that there are cases of typhoid fever in which the bowels are absolutely normal from beginning to end." One man said he had "examined repeatedly" for bacilli, but could never find any. He also said: "A microscope amply sufficient for all practical use to which any doctor need to put it can be purchased for from eighteen to twenty-five dollars, objectives and all."

Is it any wonder typhoid fever is endemic in Chicago?

E. H. Smith, M.D.

Santa Clara, Col.

MORE CONCERNING THE QUESTION OF PLAGIARISM.

To the Editor of the Medical Record.

Sir: A letter from the editor of the *Journal of the American Medical Association* assures me that Dr. Hal Forbes's paper on "How a General Practitioner may Treat Atrophic Rhinitis," was read on May 4, 1892, before the Kansas State Society, and that the figures as appearing in that journal (1891) were a misprint.

This relieves me from the imputation of having stolen and published, nine months previously, an exactly similar paper in the Medical Record (August 15, 1891) under the title "Etiology and Treatment of Atrophic Rhinitis," and places that imputation elsewhere.

This also deprives me of any more *personal* interest in the matter than should be felt by yourself and fellow-editors, your contributors, and your readers.

Yours very truly,

Jonathan Wright, M.D.

Brooklyn, June 4, 1892.

New Instruments.

A NEW, FLEXIBLE, INTRA-UTERINE ELECTRODE FOR POSITIVE GALVANO-CAUTERIZATION.

By A. LAPTHORN SMITH, M.D.,

Professor of Gynecology in Bishop's College, Montreal.

Among the most troublesome cases to be dealt with by the gynecologist who desires to give them the benefit of Apostoli's treatment are those of uterine fibroids in which the canal of the uterus is so tortuous that it is impossible to introduce either Apostoli's platinum sound or his carbon electrodes mounted on a solid stem. On some of these cases I have spent as many as eight séances of an hour each, without having been able to introduce the electrode beyond the internal os, and this while every day was of importance on account of the severity of the hemorrhage and the patient's growing scepticism as to the advantages of the treatment.

In a paper entitled "Why Apostoli's Method Sometimes Fails," which I read a year ago before the Canada Medical Association at Toronto, I pointed out that this impossibility of reaching the diseased and bleeding endometrium was due to one of several fibroids projecting into the cavity of the uterus from opposite sides, so that the uterine canal was no longer straight or slightly curved, but consisted of several curves in the form of the letter **S**.

When a patient, therefore, comes to us with fibroids, we should in every case begin by exploring the uterine canal with a flexible bougie which will follow all the sinuosities of the canal, and having found that its depth is five or six inches, we should not be satisfied with a positive electrode any shorter than this. But the question arises, "How can we introduce a metallic sound into such a canal?" Simply by covering a flexible bougie with wire, either platinum or aluminium, for a distance of one or two, or even four or five, inches from its extremity. The first cost of platinum wire would be greater, since to-day it is worth $10.50 per ounce, while aluminium wire is worth only about ten cents per ounce. In the first ones which I constructed myself, the wire was put on in the following manner: The ivory end of a medium-sized bougie was cut off and a steel wire passed down the centre until it was arrested about a quarter of an inch from the olive-pointed end; this point was marked on the outside by withdrawing the wire and measuring the distance it had entered; a needle-hole was then made at this point, and one end of the platinum or aluminium wire was threaded into it and passed out at the other end. The wire was then wound on to the bougie for the required distance, and then another pin-hole was made into which the end of the wire was again threaded into the hollow of the bougie and drawn tight. The two ends of the wire were then attached to a connecting tip to which the wire from the positive pole was fastened.

At the request of several colleagues I have handed one of the roughly made instruments to Messrs. Waite & Bartlett, the well-known manufacturers of electrodes, who have turned out a very neat instrument, as shown in the cut.

It may be objected that they will wear out, but as a matter of fact I have found that one of them will last throughout the treatment of one case, after which it may

be thrown away, the cost being so small. The best means of keeping it clean is to wash it with soap and water at the end of an application, and then to keep it in a jar of pure glycerine until required again.

The leaving of a small portion of the bougie at the end uncovered with metal is a great safeguard, as burning a hole in the uterus is thus prevented, an accident which is possible when the metallic end of the sound is pressed firmly against the fundus uteri and a heavy current turned on.

Leprosy	0	0
Mumps	0	0

Death in Blue Pills—Blue Pills and Red Tablet Triturates.—Dr. George E. Abbott, of this city, writes: "Some weeks since, at a meeting of the Post-Graduate Clinical Society, I reported an incident which seemed to interest those present, and may also the readers of the RECORD. It was a case of possible accident from the use of the bichloride of mercury tablets, 'colored blue.' One of the physicians had called attention to the advantage of the little one-grain tablet triturates, 'colored blue,' over the large ones of five or seven grains, in that the small ones gave all the solution needed for an average dressing, and one could carry in small space twenty-five or fifty dressings instead of five or ten. This reminded me of a case in which I had been using these little tablets for several days, asking the nurse to hand me some of the little blue poison tablets, etc., when I wished to make the solution. At one visit this suggestive nurse said that the patient's bowels were quite constipated, and asked if she might not give her 'some of those little blue pills.' I immediately saw the danger in the general use of these very useful little tablets, by those laymen accustomed to the old-fashioned 'Blue Pill,' and thought to have them colored red, indicating danger, thus avoiding the complication with the officinal blue pill." Dr. Abbott further says that at his suggestion a leading pharmaceutical firm in this city now manufactures the small one-grain tablet triturate, colored red, which gives us many dressings in small compass, displays a danger signal, and avoids the possibility of the blue-pill complication.

Rapid Generation.—Dr. J. V. Kendall, of Baldwinsville, N. Y., writes: "In the MEDICAL RECORD of May 7th, p. 520, is a little article on 'Rapid Generation,' by Dr. L. M. Sharp, who asks: 'Can any of the readers of the MEDICAL RECORD equal this?' to which the editor replies, 'We doubt if they can.' Now I don't propose to 'equal this,' but to give two cases of good business at 'Rapid Generation' which came under my knowledge (but not in my practice), and with both of which families I was well acquainted. The first case was as follows: A couple were married, and inside of four years they had four children, born at four confinements, evidently legitimate, as it was over nine months after marriage before the first child was born. The second case I can best describe by a short narration, as follows: I was visiting a patient with my preceptor, the late Dr. S. Pardu, of Fulton, N. Y. It was a cold day in winter, and, as the house was small and the family large, the main room was well occupied by the children hovering around the fire to keep warm. The doctor spoke to the mother as follows: 'Mrs. P——, the children are pretty thick here; how many babies have you?' Mrs. P—— replied, 'We've got only eighteen, doctor; we've lost four.' On further inquiry we learned that at three different confinements she had twins. She was an Englishwoman. Her age we did not learn; but she appeared young and fresh enough for half a dozen more. Whether she ever fulfilled the apparent promise is beyond my knowledge."

Dr. D. A. Lenes, of New Orleans, writes: "In your issue of the 7th May, Dr. L. M. Sharp, of Minneapolis, reports, under the head of 'Rapid Generation,' a case of two births in the short space of nine months and fifteen days, both at full term. I read this report with a great deal of interest, more especially since both our friend Dr. Sharp and our editor seem to doubt if any one can 'equal it.' I beg to report that at this writing I have a lady under my care who, on November 19, 1887, gave birth to one boy, and on October 16, 1888, gave birth to three girls, making a total of four births in the space of ten months and twenty-seven days, of which at this time there are three of the four children existing as living evidence, and can be seen by any one who will call on me and make the request. These three living children are the boy of the first birth and two girls of the triplets. They are perfect pictures of health and beauty, and promise to live long and prosper."

Birth of Child during Sleep of Mother.—J. B. Eagleson, M.D., surgeon to Grace Hospital, Seattle, Wash., writes: "The case of 'An Easy Birth,' reported in the MEDICAL RECORD of April 23d, by Dr. Ernest B. Sangree, of Philadelphia, Pa., brings to my mind a case which occurred in my practice three years ago. One afternoon I was called in to see a lady whom the message said had given birth to a child during the night before, but that 'the afterbirth had not yet come away.' On making an examination I found the placenta lying loose in the vagina, and readily removed it. In talking to the patient I elicited the following history from her: She was about seven months pregnant, and had had excellent health during the whole time. On the evening before, she felt some slight pains in her stomach, and, thinking that she had eaten something that did not agree with her, she took a dose of castor-oil at bedtime. She had no more pains and went to sleep as usual, and did not wake until about 3 A.M., when she felt something lying between her legs. On examining it she found that it was her baby, which had been born while she was asleep. It was a seven-months' still-born fœtus. The lady was at that time twenty-eight years of age, and had given birth to one child eighteen months before. Since then I have attended her in two confinements, both of which have been somewhat slow, one seven hours and the other nine hours. As I have never heard of a case in which the child was born while the mother was asleep, this one seemed to me to be worth reporting."

The Law Governing the Practice of Medicine in New York State, and how it is Enforced.—The many inquiries directed to the Regents' office and to the secretaries of the various State Boards of Medical Examiners indicate that the profession is largely interested in the operations of the law at present governing the practice of medicine in the State of New York. This manifested interest is accepted as of sufficient moment to warrant the publication of the salient features of the law, and at the same time to give the profession an insight into the methods and machinery necessary to its proper enforcement. The law, signed by the Governor, June 4, 1890, went into effect September 1, 1891, and has been operative since that time. It provides: "From and after the

1st day of September, 1891, any person not theretofore lawfully authorized to practise medicine and surgery in this State, and desiring to enter upon such practice," may, after the following conditions have been fulfilled, receive an order to be examined before one of the three State Boards of Medical Examiners as to his medical qualifications. 1. Applicant must be more than twenty-one years of age. 2. Must present certificate of moral character from two legalized resident (State) medical practitioners. 3. Must be a graduated doctor of medicine from some legally incorporated medical college in the United States, or have received a diploma or license conferring the full right to practise all the branches of medicine or surgery in some foreign country. 4. Must have attended at least three full courses of lectures, in different years, in some legally incorporated *medical* college or colleges. 5. Must pay twenty-five dollars into the treasury of the University of the State of New York. 6. Must present evidence of preliminary education, as follows: Either, *a*, usual academic degree; *b*, one year at academic-degree-conferring college; *c*, three years in a high school or academy; *d*, be in possession of Regents' medical student certificate; *e*, matriculation certificate required by present medical act of Canada; *f*, matriculation certificate from any university in Great Britain or Ireland; *g*, certificate of having passed examinations of any registered institution equivalent to one year in academic college or three years in high school.

All these preliminaries having been complied with, upon proof presented by the applicant, in his or her own handwriting, to the satisfaction of the Regents (on blank forms furnished on application), an order is given admitting the candidate to the next examination. Five regular examinations are held during the year (during the year 1892 there are still three regular examinations to be held as follows: June 14–17, September 27–30, and November 22–25), simultaneously, at New York City (21 Cooper Union), Albany High School Building, Syracuse High School Building, and Buffalo High School Building, and as many special examinations are ordered as are deemed necessary by the Regents, depending upon the exigencies which may arise. At these examinations the candidates are examined on the subjects of—1, Anatomy; 2, Physiology and Hygiene; 3, Chemistry; 4, Surgery; 5, Obstetrics; 6, Pathology and Diagnosis; and 7, Therapeutics, including Practice and Materia Medica. The candidate is allowed three hours' time in which to answer ten from among the fifteen questions submitted on each topic; each answer, if correct, has a value of ten points, and *each* full paper of ten questions answered must have a total value in markings of at least seventy-five points, otherwise the candidate is rejected. There are two sessions of three hours daily, each session devoted to one of the seven topics; thus, three and one-half days are requisite for completing the examination. The candidates are examined according to number, no name being allowed to appear on the answer papers; the name of the candidate is placed in an envelope marked with the corresponding number, is sealed, and left unopened until the final report of the examiners has been made.

There are three boards of State Medical Examiners, as follows, representing the Medical Society of the State of New York, Homœopathic Medical Society of the State of New York, and the Eclectic Medical Society of the State of New York.

Medical Society of the State of New York.—Physiology and Hygiene, William C. Wey, M.D., *President;* Chemistry and Materia Medica, Maurice J. Lewi, M.D., *Secretary*, 71 Lancaster Street, Albany; Anatomy, William S. Ely, M.D.; Surgery, George Ryerson Fowler, M.D.; Obstetrics, William Warren Potter, M.D.; Pathology and Diagnosis, J. P. Creveling, M.D.; Theory and Practice and Therapeutics, Eugene Beach, M.D.

Homœopathic Medical Society of the State of New York.—Pathology and Diagnosis, Asa S. Couch, M.D., *President;* Anatomy, Horace M. Paine, M.D., *Secretary*, 105 State Street, Albany; Physiology and Hygiene, A. R. Wright, M.D.; Chemistry, John McE. Wetmore, M.D.; Surgery, E. E. Snyder, M.D.; Obstetrics, William S. Searle, M.D.; Therapeutics, Practice and Materia Medica, Jay W. Sheldon, M.D.

Eclectic Medical Society of the State of New York.—Obstetrics, Hugh J. Linn, M.D., *President;* Surgery, Edwin S. Moore, M.D., *Secretary*, Bay Shore; Anatomy, William L. Tuttle, M.D.; Physiology and Hygiene, Robert Hamilton, M.D.; Chemistry, Harry B. Smith, M.D.; Pathology and Diagnosis, John P. Nolan, M.D.; Therapeutics, Practice and Materia Medica, *Vacancy.*

They are appointed by the Regents from nominations submitted by the State, Homœopathic, and Eclectic Medical Societies, for a term of three years, for every vacancy two names being submitted by the societies. The principal work of the examiners is to formulate questions for examination purposes and to mark the answers thereto. The questions submitted at each examination are the same for all candidates, excepting on the seventh topic (Therapeutics, Practice and Materia Medica), three sets of questions being furnished at each examination, each set representing the views of one of the three legally incorporated schools of medicine in the State on this subject, the candidate receiving the set for which he had expressed a wish in his original application for license. The questions to be used at the various examinations are decided upon as follows, those previously secured in a similar way having become exhausted: The Regents issue a notice requesting each of the twenty-one examiners to forward, on or before a certain date, sixty questions on the special topic to which each is assigned; subsequent to this date the Questions Board, consisting of six members, two from each board, is called in session. The questions on the seventh topic are handed to the two members representing their special board, who, as previously stated, and as particularly specified in the law, have complete charge of this subject. With the other six subjects, one hundred and eighty questions having been submitted in each, the Questions Board acts as follows, taking Anatomy, for instance: The secretary reads a question alternately from each of the three papers submitted by the examiners in this topic, and unless each receives the unanimous vote of all present it is stricken from the list of available questions. The one hundred and eighty questions having passed through this process, are arranged in sets of fifteen, each set is numbered and sealed, and thus at one sitting, lasting, however, many hours, an average of ten complete sets of questions is prepared, thus providing for ten future examinations. These sets of questions are placed in the custody of the Regents, who, as the time for the next examination approaches, call upon the secretary of the Questions Board to review the printer's work after the questions are put up in type. The examinations proper are conducted by a sworn official of the Regents' office who is not a member of any one of the State boards of medical examiners. As soon as the examinations are concluded the answer papers are delivered to the secretary of the board selected by the candidate in his application, and by him in turn sent to the different individual examiners, who return the papers with their markings to the Board of Regents; these answer papers thereupon become a part of the public records of the State. If a favorable report is made by all of the examiners on the answers of any applicant, a license is immediately forwarded to his address, thus enabling him to register at once and commence the practice of his profession. The last examination was concluded May 6th, and on May 14th the licenses were forwarded from the Regents' office to the successful candidates. Arrangements are now being made for the next examination, which will enable the Regents to forward these licenses within five days of the close of the examinations. The income accruing from this law goes to the Board of Regents, who after paying

all proper expenses will, if ever there should be a surplus, apportion the money among the twenty-one examiners according to the number of candidates examined by each. Graduates in medicine who have been licensed by State examining boards of other States *of the United States only*, on convincing the Board of Regents that the standard of requirements adopted by the board of examiners which granted them the license is substantially the same as in New York State, may, upon the payment of $10, have such license endorsed. The following summary of the laws has been made :

1. The University of the State of New York is the only organization having authority to issue licenses to practise medicine in this State after September 1, 1891. These licenses must be registered by county clerks, on application. (*Laws of New York*, 1890, ch. 507, § 8–9.)

2. Licenses issued before September 1. 1891, can be registered only as follows : *a*, A diploma granting the degree M.D., issued before September 1, 1891, by an incorporated medical college *in this State*, is a license to practise medicine and must be registered on application. (*Laws of New York*, 1889, ch. 647, § 2.)

b, A diploma granting the degree M.D. from a medical college *out of the State*, or a license to practise medicine in some foreign country, can be registered only if it was endorsed between June 18, 1880, and June 24, 1890, by an incorporated medical college of the State of New York or by the University of the State of New York, or if between June 24, 1890, and September 1, 1891, it was endorsed by the University of the State of New York. (*Laws of New York*, 1880, ch. 513, § 4; 1887, ch. 647, § 2; 1890, ch. 500.)

3. Students who had matriculated in a New York State medical college prior to June 5, 1890, and had not received the degree M D. prior to September 1, 1891, to be exempt, must have filed a certificate with the University of the State of New York before August 4, 1891. (*Laws of New York*, 1891, ch. 311.)

Licenses of such candidates may be registered as follows : *a*, A diploma granting the degree M.D. from a New York State medical college issued after September 1, 1891, can be registered on presentation of a certificate from the secretary of the University of the State of New York that the applicant had matriculated in some medical college of the State prior to June 5, 1890. (*Laws of New York*, 1891, ch. 311.)

b, A diploma granting the degree M.D. from a medical college not in the State, or license to practise in a foreign country, if endorsed by the University of the State of New York, can be registered on presentation of a certified copy of a certificate filed with the secretary of the University of the State of New York that the applicant had matriculated in some medical college of the State prior to June 5, 1890. (*Laws of New York*, 1891, ch. 311.)

All diplomas issued by medical colleges in this State prior to January 1, 1880, which are presented for registration after this date, should be referred to the University of the State of New York for examination before being registered.

And further, to quote the exact wording of the law :

§ 10. Nothing in this act shall be construed to interfere with or punish commissioned medical officers serving in the army or navy of the United States, or in the United States marine hospital service while so commissioned, or anyone while actually serving as a member of the resident medical staff of any legally incorporated hospital, or any legally qualified and registered dentist exclusively engaged in practising the art of dentistry, or interfere with manufacturers of artificial eyes, limbs, or orthopedical instruments or trusses of any kind from fitting such instruments on persons in need thereof; or any lawfully qualified physicians and surgeons residing in other States or countries, meeting registered physicians and surgeons of this State in consultation, or any physician or surgeon residing on the border of a neighboring State, and duly authorized under the laws thereof to practise medicine or surgery therein, whose practice extends into the limits of this State; providing that such practitioner shall not open an office or appoint a place to meet patients or receive calls within the limits of the State of New York; or physicians duly registered in one county of this State, called to attend isolated cases in another county, but not residing or habitually practising therein.

Appended will be found the examination results thus far obtained :

Number of those who fulfilled all requirements and received license	34
Number of applications still unacted upon	10
Rejected for failure to reach seventy-five per cent. at final medical examination	1
Deficient in preliminary education	6
Had never attended three full courses of lectures	4
License withheld because of moral reasons	1
Total number of applicants for license to practise medicine to date	56

Addenda.—All examinations are conducted in English, unless the applicant expresses a desire to be examined in Latin. In that event the application, with the reasons therefor, is placed before a committee consisting of the presidents of the three boards, whose decision is accepted by the Board of Regents. The candidate must pay the expenses of translation. Whenever it is found necessary to obtain the opinion of the boards of examiners, the University authorities are requested to confer with a subcommittee of the conference, consisting of the president and secretary of each board, who are the executive committee of the boards. The boards proper meet twice in each year.

A syllabus is in course of preparation and will be issued shortly. A candidate having failed, whether in one or all seven branches, his application for license is rejected. On re-examination no fee is exacted, but the candidate must pass the examinations on all seven topics regardless of the number he passed at the previous examination. Appeal for a reopening of any examinations may be made to the Regents of the University.

Indications point to a class of from fifteen to twenty applicants at the next regular examination, June 14, 1892.

By order of the State Board of Medical Examiners, representing the Medical Society of the State of New York.

WILLIAM C. WEY, *President.*

MAURICE J. LEWI, *Secretary.*

Professional Fees among the Israelites.—On this subject there is a curious document, of which the Hebrew original is lost. It is the "Ecclesiasticus" of the Son of Sirach, Jesus by name, a book not accepted by Jews or Protestants as part of the Bible, but included in the so-called "Apocrypha." Another Jesus, grandson of the above-named, has left a Greek version of it, and St. Jerome, who says he saw it in its original Hebrew, has translated it into Latin. The Talmud contains some fragments of that original. The opening words are in the Vulgate as follows : "Honora medicum, propter necessitatem; etenim illum creavit altissimus." (Honor the physician, because thou hast need of him; for he was created by the Most High.) In this passage "honorare," it has been remarked, means not only to "respect," but to "give honoraria" (fees). In this sense the Greek of the Septuagint corresponds with the Latin. The passage proceeds : "A Deo est enim omnis medela et a rege accipiet donationem." (From God indeed comes all healing, and the king will crown it with presents.) Again : "Disciplina medici exaltabit caput illius et in conspecta magnatorum collaudabitur." (The culture of the physician will exalt his head, and in the presence of princes he will be praised.) Yet again : "Altissimus creavit de terrâ medicamenta, et vir prudens non abhorrebit illa." (The Most High has made medicines to spring from the

earth, and the wise man will not abhor them.) After a eulogy of the virtues of these medicines, especially as prepared by the apothecary, the passage resumes: "Etenim Dominus creavit illum (medicum) et non discidat a te, quia opera ejus sunt necessaria." (For the Lord has created him [the physician], and let him not abandon thee, for his works are necessary to thee.) The English version from the Greek of the Septuagint is substantially the same as the above rendering from the Vulgate. See "Archeologie Médicale de l'Égypte et de la Judée," par le Dr. Beugnies-Corbeau (Liége, 1891).—*The Lancet.*

One "Dr." John Malok, of Chicago, incorporated a "German-American Homœopathic College" at the lavish expenditure of $6.50. The college was opened, with prayer and located over a beer saloon.

> "The spirits above were spirits divine;
> The spirits below were spirits of wine."

Soon after the "opening" of the "college" these spirits malign began to persecute him. They inserted advertisements in Berlin (Germany) papers offering diplomas cheap. Through their machinations a midwife deposited $400 with the college as a fee for a professorship, which somehow disappeared. The German advertisements caused the deposit and disappearance of $100, which a deluded man says he paid to "Dr." Malok, but the latter claims to his malign enemies. This "truly good" man has been sued for several similar disappearances of cash. The college is defunct, but the hand of the law is lifted threateningly over "Dr." Malok, who will probably never get another Hahnemanniac diploma nor give one.—*Medical Standard.*

A Visit to the Pasteur Institute in Paris.—The Institute is quite a fine large building standing back from the street. On the grass plot in front is a figure of a boy struggling with a mad dog, in bronze, which typifies at least one branch of the work done in the Institute. We entered a large waiting-room at the side, which contained about sixty patients of all nationalities. I noticed among them two Arabs in their native dress, a Chinese, a Japanese, besides several English people. The treatment is gratuitous only, so rich and poor have alike to wait their turn. The porter took our cards into the professor's room, and in a few moments we were ushered into the presence of the great man. He greeted us very kindly, and after a few remarks called an assistant, who showed us about a bit, and explained the treatment to us. A very careful record is kept of each patient, the state of the dog, site and extent of the wounds, date when bitten, date of commencement of treatment, etc., all being recorded. It seems bites about the face are considered the most dangerous. As a rule, from twenty to sixty injections in all are given, at intervals of a day or two. The strength of the solution is gradually increased as the treatment goes on, the duration of the treatment depending on the site and character of the wounds. The fluid itself is an opaque, milky-looking substance with but little odor. The patients come in in turn, with the clothing about the abdomen loosened so that a small area of skin can be reached on either side. The patient is held by and leans on an assistant, as most start when the needle is introduced. The site of the injection having been cleansed with a solution of carbolic acid, about 10 c.c. of the fluid is injected deeply into the tissues with an ordinary large hypodermic needle. As a rule, an injection is given on either side of the abdomen. Pasteur is a small, rather spare man, with a much wrinkled, yet kindly, face, and gray hair. I was surprised to notice that he has very little power over the left side of his body, and that his speech is affected, so that it is difficult to understand what he says. This condition is the result of a "stroke" he had six years ago. The work of the Institution is done by assistants, Pasteur being able to do but little.—Paris Correspondent of the *Montreal Medical Journal.*

Dr. E. S. Barrows, who died on March 11th, in Davenport, Ia., at the age of ninety-three, some years ago caused the following epitaph to be engraved on the monument over the spot where his wife was, and he was to be, buried: "All who sleep here still exist as material constituents of the Universe. Hope may, but belief should not, transcend experience."

A Doctor Expresses His Sentiments.—A physician of Brussels has got himself into trouble by going to a variety show and giving utterance to his disapproval of certain improprieties of the ladies with short skirts. The audience did not appreciate the timeliness of his remarks and proceeded to turn him out. He resisted and a general row ensued, which resulted in the doctor being locked up for the night and fined 150 francs for disturbing the peace, in addition to having to pay the proprietor of the show for the damage done to furniture and beer-glasses.

A Great Scandal at the Faculty of Medicine of Paris.—There is held periodically at the Paris Faculty of Medicine a competitive examination for the filling up of any vacancies that may occur in the list of *professeurs-agrégés* in medicine or surgery or obstetrics at the metropolitan and provincial faculties. The examining board is composed of professors of the Paris and provincial faculties, the president nominated this year by the Ministry of Public Instruction for the examination in medicine being Professor Bouchard. When the result of this very difficult and long competition was announced a fortnight ago, the absence of certain well-known names from the list of successful candidates was much commented on, and charges of favoritism and infringements of regulations in the conduct of the examination were boldly formulated both in the lay and professional press. The choice of the professors composing the Board of Examiners lies with the president of the board, himself nominated as above mentioned by the Minister of Public Instruction. A general charge is made that the discretionary power thus conferred on the president is taken advantage of in order to form a jury whose sympathies will naturally incline toward any candidates favored by the president. It is further pointed out that the choice of a president at this year's *concours* was particularly unfortunate, seeing that Professor Bouchard, without having the title, exercises the functions of the technically suppressed post of inspector-general of faculties and schools of medicine. The irregularity alleged to have occurred in the conduct of the examination consists in this—that it was postponed for twenty-four hours pending the recovery from indisposition of Professor Sée, a member of the jury. When M. Germain Sée had recovered he could only attend during three days, and the proceedings were continued without filling up the vacancy caused by his definite retirement, which constituted yet another irregularity. Of the five successful candidates for the Paris faculty it is said that three are pupils of M. Bouchard, that three of the five are not hospital physicians, and have published no particularly important works, and, finally, that three out of the five unsuccessful candidates are not only hospital physicians, but are well known for their valuable contributions to medical science. For these various reasons the unsuccessful competitors have sent a petition to the Minister praying him to annul the choice of the examiners. That their contention merits consideration is probable from the fact that no less a personage than Professor Cornil presented the discontented phalanx to M. Lesage, Avocat au Conseil d'État, who is to champion their cause.—*The Lancet.*

Dr. Constantin Paul's new development of Brown-Séquard's principle has been received with such universal condemnation that one begins to think there is something in it. All genuine discoveries in medicine are met with incredulity and opposition, while only Koch's lymph, and such, evoke the instant and universal enthusiasm of the medical profession.—*Times and Register.*

THE PROBABLE ERRORS OF FOOD INVESTIGATIONS.

By CHARLES E. WOODRUFF, M.D.,

ASSISTANT SURGEON, UNITED STATES ARMY.

THERE are unavoidable errors that enter into any operation having for its object the determination of the numerical value of a quantity. For instance, the exact latitude of a place can never be known, and if a dozen determinations are made, probably no two will agree. The mean of the various values and its probable error can be calculated by the higher mathematics. If the probable error is one-tenth of a second, we know that the calculated mean value of the latitude is within one-tenth of a second of the true value. In simple operations, as the measuring of the length of a bar of iron, or in those in which the method is nearly perfect, the probable error may be very small, but in complex or crude operations it is often so large that the numerical result obtained may be a mere approximation. No two investigators reach the same result in their efforts to find the quantity of food requisite for a man in health. The operations performed in such investigations are often so complex, and the sources of error so numerous, that the results obtained differ widely. If the various values obtained were combined to calculate the mean and its probable error, we should find that the latter is entirely too large to be neglected either theoretically in scientific studies of food, or practically in devising an economical dietary for schools, prisons, almshouses, or armies. Many of the works treating of food fail to point out the errors that necessarily arise, though they state that the results given are averages and often mere approximations. A study of the various errors that enter into food investigations is therefore of considerable importance to everyone concerned in such problems.

Methods of Determining Daily Food Values.—There are four methods used in determining the amount of food required by a man in health.

First, by collecting and analyzing all the excreta, obtaining the amounts of carbon and nitrogen therein contained. These values would, therefore, be the quantity to be daily supplied in the food.

Second, by measuring the food consumed by persons in the lower walks of life, who live in presumable health, and whose poverty necessarily limits both the quantity and variety of food to the barest needs of existence.

Third, by measuring the food consumed by large bodies of men who are fed from one kitchen, as in prisons or almshouses. This method is, of course, merely an extension of the second.

Fourth, by measuring the amount of energy expended by men, including work done voluntarily and involuntarily, and heat radiated or otherwise lost, and from these calculating the amount of energy required in the food to replace the expenditures.

It is evident that all these methods must involve serious errors, that are due not only to the crudeness of the methods themselves, but also to the complex nature of the problem and its numerous details, and it is these sources of error that are detailed below.

Chemical Composition of Foods.—The first method presumes that the carbon and nitrogen of a given article of food are always known. They have been accurately determined in particular cases, yet the results of different chemists vary within limits that are often far from the average. Such variations are, in the first place, partly due to unavoidable errors of the chemical apparatus, for the methods used to determine these values are extremely complex, and due allowance must be made for instrumental errors, leakage, etc. In the second place, the vetetables and meats themselves must be subject to variations in chemical composition due to variety or species, climate, season, heat, moisture, cultivation, and the thousand and one causes which promote or retard nutrition and growth of plants and animals. We are, therefore, not sure that a pound of potatoes, for instance, contains 23.1 grains of nitrogen and 770 grains of carbon, as stated by Payen, or whether much more or less. The same may be stated of all the staple articles of diet, and a numerical value may be given to these discrepancies in a few cases. Beef contains 13.125 grains nitrogen per avoirdupois ounce, according to Payen; but according to Parke, beef, as supplied to the soldier, contains but 10.35 grains, each estimate having a variation of ten per cent. from the mean. There is a possible variation of forty five per cent. of the mean of the nitrogen in salt pork (18 grains per ounce) and fat pork (6.8 grains per ounce) as given in Parke's tables, and it is evidently impossible to estimate from such figures the composition of any given specimen of this article. In the case of peas, bread, and flour there is much greater uniformity, yet bread when fresh baked contains so much water, which it loses in a few days, that it alone would cause considerable inaccuracy in a dietary.

Chemical Energy and Heat Value of Foods.—The fourth method above presumes that the heat value or potential energy of the food is accurately known—an unwarranted assumption. The determination of the chemical energy of any substance is an intricate problem, and though it may be obtained with some degree of accuracy by the calorimeter, the results obtained have their errors, which are chiefly instrumental. Again, the total energy of the articles of food is not liberated in our bodies, for the products of combustion in our bodies are not the same in many cases as the products of combustion outside our bodies. This is particularly so in the case of nitrogenous food, whose lowest degree of oxidation is the form of urea, and a large portion of the nitrogen is excreted in the form of much higher and more complex compounds—in the digestive fluids, the vapors from the lungs, the epithelium, and fluids from the skin and mucous surfaces. The energy lost through these avenues is not known, nor can a close approximation be made in the case of these complex and unknown substances, and the necessary corrections cannot be applied. It can only be said that the total energy of food is not the same as the available energy, or the amount that can be given out in heat and work, and this source of error must cause considerable variation in the amounts of energy needed in foods, as determined by different investigators.

It has already been stated that the chemical composition of different varieties of the same article of food will vary, and of course the same may be said of the potential energy. A pound of beef from one animal may yield more energy than a pound from another, or an ounce of wheat from one district more than an ounce from another. This variability, due to the causes which have already been mentioned as influencing growth and develop-

ment, will always cause some uncertainty as to whether the total energy of the food supplied is equivalent to the energy expended per day by a healthy man, even should the latter amount be accurately determined.

The Actual Available Energy of Foods.—We have already given the name of available energy to the total energy of food which can be given out in our bodies by oxidation to the simpler substances excreted. In a steam engine the fuels supplied are compounds of carbon and hydrogen chiefly, and these are oxidized in the main to the form of carbon dioxide and water in the more perfect contrivances. Of all that energy so liberated but a small proportion is utilized in the form of work by the engine, because the sources of water are numerous and unavoidable. The total amount that can be used in a perfect machine might be called the available portion. As the machines are never perfect, the available energy is not all used. An animal, likewise, receives fuel as the engine, but the fuel is more complex. The hydrocarbons and carbohydrates are theoretically burned to the form of carbon dioxide and water, while the nitrogenous foods are chiefly burned to urea or still higher forms. In the animal, unlike the engine, nearly all of this energy is available for the production of heat and work, because the sources of waste in engines are not found in the case of animals. The perfect animal has a far higher efficiency than the perfect engine, but as it is a mistake to regard the latter as perfect and capable of utilizing all the available energy, so it is also an error to assume that animals are perfect machines, and able to convert all the available energy of the food into heat and work. There are many ways mentioned below in which the available energy of our food may be lost.

Digestibility of Food.—The variability of food, aside from its chemical composition, but in regard to its digestibility, introduces a variation in primary assimilation and a loss of the otherwise available energy. Every article of food contains a certain portion which is indigestible; for instance, the cellulose of fruits and vegetables and the tough tendinous portion of meats, and in some cases even the meat itself—the muscular fibre—is in such a hardened condition that it resists the digestive fluids. This indigestible portion is often intimately mixed with the digestible, and its amount varies within comparatively great limits. We cannot tell at a glance how much this portion is, and we often find much undigested food in the fæces when no reasonable explanation can be given, except that this portion was large in amount, and so mixed with the rest as to prevent the digestion of the whole. Again, there are many articles of diet, as, for instance, peas, corn, and beans, which, though ordinarily digestible by a healthy stomach, become exceedingly indigestible through age, or carelessness, or ignorance in preparation or preservation, and often through unknown causes. It is certain that highly nutritious and wholesome articles of food often pass through a healthy intestine totally unchanged, and much energy which we would judge to be available for the production of work be wasted.

Assimilation.—When food is eaten it is not necessarily assimilated, for there are often great variations in the digestive power of healthy people. It is rare to find a person whose health and habits are so uniform that each day is simply a repetition of the preceding day, and who has no variation in his comfort or power of work. Every man meets daily with occurrences which vary his appetite, digestion, and excretion. If a healthy man were to eat each day exactly the same number of grains of the same kind of digestible food, it is not improbable that in no two days would the amounts assimilated be exactly equal. There are many conditions which vary the primary assimilation, as, for instance, the amount of blood supplied to the digestive organs, resulting from the temperature and condition of the skin, the coincidence, during digestion, of rest or of light or heavy work, or any of the multitude of little causes combining to take blood from these organs. If great fatigue or exhaustion existed previous to the ingestion of food, digestion may not only be delayed, but greatly diminished. The condition of the stomach is of importance, for if too short a time has elapsed since the last meal, or if the organ were previously abused by improper food, its power is certainly less than it should be. It has long been known that a state of fever prevents secondary assimilation—the hair, nails, and other tissues ceasing to grow; and it is now known that fever may entirely suspend primary assimilation also, the stomach and intestines being for the time useless organs with inert digestive fluids. It is, therefore, reasonable to suppose that slighter variations in the condition or tone of the system may cause impairment of the power of the stomach and intestines and a loss of good food. There are few people who eat properly. The stomach is as much abused as any portion of our anatomy. Hasty eating and faulty mastication are the chief causes of the enormous number of cases of "dyspepsia." Every physician can recall cases where vomiting for some cause has taken place many hours after a meal, and the vomited matters contain huge pieces of meat that have been hastily swallowed and resisted the power of the gastric juices. In such cases primary assimilation must be faulty and a waste of food energy take place. There are, in fact, many ways in which variations in the condition of the body, or of particular organs, or of the nervous system, will cause variations of digestion, and make it impossible to foretell how much of the food ingested will be assimilated. From these and still other causes we see why it is that a microscopic examination of the fæces of a healthy person consuming proper food, may reveal much of that food undigested.

Cooking.—Cooking is seldom uniform. Other conditions of the food being unchanged, a good cook, instead of making food more digestible, will occasionally make it less easily digested. Indeed, a little carelessness may make a wholesome article entirely indigestible. The waste of available energy may become enormous where the cook is unskilled, where he is ignorant or stupid, or where faulty methods of cooking are employed. The frying-pan may so harden food and coat each particle with grease to such an extent that no gastric fluid will have the least effect upon it. This possible loss of available energy by cooking should therefore be always taken into consideration.

Errors in Measuring Excreta.—In determining the amount of carbon and nitrogen excreted, the urine, fæces, and exhalations are collected and analyzed. In the case of the urine, of course, extreme accuracy is obtained, and as the urine is the chief vehicle for the excretion of nitrogen, we gain valuable knowledge from this source alone; but there are other channels for the excretion of nitrogen. Ammoniacal and other nitrogenous vapors and fluids from the mucous and cutaneous surfaces carry off a certain percentage of nitrogen, and though presumably small in comparison to the nitrogen of the urine, they introduce an error which vitiates the accuracy otherwise obtainable.

The apparatus used to collect the exhalations is extremely complex, and each increase in its intricacy introduces instrumental errors that throw some doubt upon the numerical results obtained.

It is in the case of the fæces that the greater error is found, for here, as above noted, there is much uncertainty due to ignorance of the digestibility of food. The carbon and nitrogen of the fæces is not all excreted, in the limited sense of the term; but some of it represents the undigested portion of the food, and there is no accurate way of determining which portion is waste and which portion is an excretion. This error is of importance if we wish to find out how much carbon and nitrogen are actually excreted, but practically it is of little value if we want to know the actual amount of food necessary, because, whether they are in the waste food or in excreted compounds, they must be supplied in the food. The

error in the latter case may be quite small, for the daily fecal discharges in any one case are quite constant in amount, leading us to suppose that the daily undigested residue may be quite constant; but, on the other hand, the causes already mentioned may make it vary within quite wide limits.

Errors in Measuring Energy Wasted.—Omitting the waste in the food from the causes already mentioned, it has been calculated that if all the food is consumed to carbon dioxide, water, urea, etc., there are 2,200 calories of heat available. This energy is expended as follows, according to Professor Chapman:

	Per cent.
1. Warming the ingesta, food, water, and air, about	7
2. Work done by respiration, circulation, and muscular effort.	16
3. Vaporizing water from skin and lungs, about	27
4. Radiation and conduction, about	50
	100

Knowing the amounts of food, water, and air ingested, and their temperatures and specific heats, the heat absorbed by them can, of course, be calculated with some degree of accuracy, and the same may be said of the heat taken up by watery vapor from the surfaces of the body. In the case of the work done, the problem is much more intricate and the results are not so trustworthy.

It is in the items of radiation and conduction that the greatest error enters, so great indeed that the results obtained can be regarded as only approximations, and as the heat radiated is fifty per cent. of all the energy expended, any inaccuracy greatly affects the general result. There is no way of obtaining the heat radiated or conducted from a man in a given set of circumstances, and even if there were, there are so many ways in which that radiation is varied that only an estimate can be made in the case of all other men.

The one item of the kind of clothing worn exerts a vast influence on the radiation and indirectly on the food necessary to keep in health. For instance, the partially civilized Indians in the colder parts of the country, having forsaken warm furs formerly worn in winter, have taken up cheap cotton clothing, which is scarcely any protection whatever, and as the food has remained the same, the poor grade of clothing has been accused as one of the causes of the immense number of cases of phthisis they now develop.

The temperature and moisture of the air, the force of the wind, the amount of exercise taken, peculiarities of perspiration, now reduced and again excessive, and various other minor conditions, affect the heat radiated; but besides these there are personal peculiarities which deserve notice.

It is possible to place two men in the same situation in a cold climate and find that one may lose by radiation two or three times as much heat as the other. Part of this difference may be due to habit, for he who is accustomed to exposure has so drilled his nerves that they do not transmit sensations of cold as acutely as in the case of him who is accustomed to warm surroundings. As a result of this nerve benumbing, there are no rapid vascular changes through the vaso-motor nerves, the superficial capillaries remain contracted and contain but little blood to lose heat by radiation. Dr. H. C. Wood, in his book, "Brain Work and Overwork," refers to a guide who slept on the ground, during a cold night in the mountains, without any covering, not even his coat, while the doctor was enveloped in blankets.

In addition to the factor of habit, there is another individual factor influencing radiation, but due to the amount of surface exposed to cold and the condition of the man as to emaciation or obesity. In cold countries there is an immense difference in the amount of clothing worn by the residents; some, chiefly the obese, are seen without coats or gloves; while others, usually slightly built men, are muffled to the ears in furs. A thick layer of fat under the skin is sufficient to account for much of this difference. The fat prevents loss of heat from subjacent structure in the same way that the fat or blubber of warm-blooded aquatic mammals is necessary to keep them warm. In addition to the fat there is another factor—the amount of surface exposed to radiation as compared with the weight of the person. There is a well-known mathematical law, that as the size of a body increases the surface increases in the ratio of the square of the linear measurements, while the weight or bulk increases in the ratio of the cube. In other words, there is less surface exposed to radiation in an obese man than in a thin man of the same weight but of different stature. The fat man will, therefore, lose less heat per hour than the thin man, according to the same rule that a hundred pounds of red-hot iron will take far longer to cool in one mass than if it were drawn out into wire. It is this law of the relation of surface to weight, or, in other words, relation of surface to amount of heat to be radiated, that partially accounts for the well-known fact that thin men usually eat more than fat men. We constantly hear the cause given for the effect in the statement that a certain person "eats so much that he makes himself thin carrying it." In the case of the smaller animals there is another factor which antagonizes the above rule, or, rather, makes up for it. The smaller an animal is, the more rapid are the respirations, pulse, circulation, and tissue changes, from which we may presume that heat production is more rapid per pound of weight, making up for the greater proportional loss of heat from the greater exposed surface in proportion to weight. In the case of growing animals, there is great activity of tissue-change due to growth and development, and the extra heat thus produced shows why it is that children frequently require far less covering at night than adults. As a general rule, the larger the animal, the smaller the amount of food energy required and consumed per pound of body-weight.

The above facts make it evident that there is much difficulty in obtaining reliable estimates of the amount of food one man should consume, based upon data of the energy lost by another man in a certain combination of surroundings.

Variations in Daily Consumption of Food.—Observations show that the daily amount of food a man consumes is far from uniform. Dr. Flint's experiments on the pedestrian, Weston, in 1870, give an average of 339 grains of nitrogen consumed daily for fifteen days, yet the largest and smallest daily amounts were 641.71 grains and 144.70 grains, variations of eighty-nine per cent. and fifty-eight per cent. respectively from the average. It is not possible from these figures to tell what is the proper amount for a man. Pavy, in his work on food, states that the nitrogen ingested varies from 250 to 350 grains daily. Assuming 300 grains as a standard, we may be falling into the error of giving too little at one time and wasting food at another.

There is in addition an individual variation due to differences in appetite. Healthy men, performing equal amounts of work and similarly situated, are known by experience to consume vastly different quantities of food. Indeed, one man may eat so little and yet keep in presumable health, that, compared with the heavy eater, he may throw all scientific figures into utter rout. Part of this difference may be due to obesity or leanness, but again it seems to follow no rule whatever. These variations make the results, according to the second method, inaccurate to a certain unknown degree.

Inappropriate Food.—In measuring the food consumed by the poor, no account is usually taken of the fact that the food may be highly inappropriate and producing disease. Knowledge on this point is becoming more exact every year. Though we have long recognized the partial or entire dependence on the food of such diseases as scurvy, gout, rheumatism, and rickets, it is only in more recent years that notice has been taken of many other diseases which may have been due to im-

proper food. Dr. Frank Woodbury, in a paper read before the Philadelphia County Medical Society, refers to facts showing a decided connection between diseases and foods, particularly the nitrogenous. For instance, cancer, Bright's disease, and acute inflammations are promoted by excess of nitrogenous foods, while anæmia, neurasthenia, atonic dyspepsia, phthisis, and eczema are favored by a deficit of nitrogen. It is possible that a carcinoma, a case of tuberculosis, or fatty degeneration, or anæmia of malignant type, may have taken its remote origin in a depressed vitality of one or more organs due to a long-continued improper or scanty diet, the organs never having recovered from their original prostration. In other words, the men whose diet is measured may be in health, but they may be undermining that health to a dangerous degree and yet not have felt any of the effects of disease. This fact is illustrated by those occasional cases of children who are fat and healthy in appearance, yet are at the time being impoverished by improper food, and shortly develop rickets. It is not enough to say that a certain diet keeps a man alive, but it must keep him in perfect health, and until the etiology of every disease is wholly known, we are uncertain, in a given case of sickness, what degree of importance to attach to the diet that may have been previously taken.

In addition to actual diseases generated by improper food, there is the lessened vitality or resisting power which may be induced. Some men will resist infection and throw off disease where others cannot. The whole life of an animal is one continued struggle against enemies, and the studies on phagocytes are showing how this struggle is kept up. The animal should, by proper nourishment, be kept in the highest state of efficiency. It is well known that among the poor disease is much more prevalent than among the well-to-do. Epidemics generally obtain a foothold among the cottages before attacking the palaces. In addition to the general unsanitary condition of the dwellings of the very poor, their scanty and often improper food may be the chief cause of their greater susceptibility to disease. In view of these facts we cannot give much scientific value to the determinations of the food of the very poor, as it probably errs not only from the proper amount, but the proper quality.

Though knowledge of how, where, and when oxidation takes place is becoming more exact, it is far from perfect. The various changes through which nitrogenous substances pass in breaking up to simpler forms are being wrought out with some evidence of accuracy, but there is much to be learned on that subject alone, and as yet we cannot be sure we are supplying the proper kind of nitrogenous food. Foods now considered nourishing may in a short time be found to be worthless. Liebig's extract of beef, beef tea, and various other substances, though of considerable value as stimulants, were but a short time ago given a high nutritive value. Similar considerations enter into the question of when oxidation takes place. Theories on this subject are changing. It was not so long ago that it was supposed that the lungs were the furnaces of the body, though it is now believed that oxidation takes place wherever there are capillaries to carry oxygen, the red corpuscles acting as the flues which supply the draught. Exact knowledge on this subject would certainly enable us to regulate a diet with much more accuracy than at present. Indeed, it may be essential to know how and where the food is burned, if we are to draw any comparisons from the stoves and furnaces. Wood in a coal-burning furnace, or coal in a wood-burning stove, may burn, but with such a great loss of efficiency that, even if supplied in abundance, it may be the next thing to being worthless as far as the supplying of energy is concerned. In like manner food may be supplied in abundance, but in such combinations that oxidation is imperfect and disease result. Oxaluria, lithæmia, rheumatism, and other affections may in part be due to just such errors.

There is to be considered also the uncertainty as to the time when oxidation takes place. The body contains a surplus of energy sufficient, providing water be applied, for the maintenance of life for two weeks, or even much longer, if we are to rely on the professional "fasters" who starve themselves for exhibition purposes. We have but little knowledge of how this surplus is drawn upon in cases where the food is insufficient, nor any knowledge of whether it is used at all where there is an abundance of food. Oxidation is continually going on, yet food is applied but thrice daily, and each day's supply may be used immediately or it may be added to the surplus store and the whole drawn upon constantly. The uniformity of the temperature of the body and the store of energy ready for use is somewhat analogous to the store of heat in some of the old cathedrals of the old world. The interiors of some of these vast structures are said to preserve an invariable temperature throughout the whole year. The heat lost or gained by the opening of doors to admit worshippers bears so small a ratio to the whole heat within, that changes are insignificant and easily rectified by other causes. The temperature of the body is uniform, though heat is being constantly lost, and the store of energy seems to undergo but little change, though being constantly used and occasionally augmented. Some knowledge of the minutiæ of the changes going on would evidently be of some service in regulating the diet. If the assimilated food is to be used at once, or should be used at once, the most economical diet would be that which could be most easily burned; but if all the assimilated food is to be added to the stores of energy, the most economical would be that which is most easily converted into the tissues of the body. The absence of the knowledge causing improper proportions and variety of food, must occasion a loss of efficiency, and the error, though it may be small, should never be forgotten. It is probable that this question of the time at which oxidation takes place may be one of the causes of the wonderful contradictions among scientists, even at this late day, on the subject of alcohol, whose food value has confidently been stated as zero, and again just as confidently given at a very high figure. Even should we know exactly how, where, and when the assimilated food is used, we would not be justified in limiting a man to the minimum quantity containing the necessary energy, but should be guided by the questions of digestibility and other variations already discussed.

Estimates of Amount of Food.—Each of the numerous sources of error may in a particular case be insignificant, and all the slight errors may happen to neutralize each other and the estimated food be proper for a man in certain circumstances. But they may all act in one direction and the estimated food be far from correct. The errors have been given different values by different men, for the following estimates of the amount of the alimentary principles required daily have a wide range: In albuminates there is a maximum of 7 ounces (Parke) and a minimum of 3.52 ounces (Ranke), or an error of thirty-three per cent. of the mean. In fats there is a maximum of 5.942 ounces (Dalton) and a minimum of 2.50 ounces (Playfair), a variation of about forty per cent. of the mean. In carbohydrates there is a maximum of 20 ounces (Playfair) and a minimum of 8.46 ounces (Ranke). Such great variations as forty per cent. are entitled to much consideration. The above figures are given, as far as possible, for men doing equal amounts of work.

Considering all the sources of error in the experiments and other methods of gaining information, we see that the probable error of the average of the determinations of food necessary for men in health is probably very large and not to be ignored. The only conclusion we can draw is, that for the present we do not know enough to make a perfectly accurate dietary. Though such a conclusion is somewhat pessimistic, we know that in time our knowledge will become much more accurate and the probable error much smaller, and, indeed, perhaps small enough to

be ignored practically. For the present, the dietary should be more liberal than the averages of the experiments demand, and broad enough to cover any deficiency due to error. Even after the most accurate knowledge is obtainable there are other considerations, as of the variability of work and climatic changes, which may prevent the proper application of that knowledge. The factors that enter into the question are so numerous and so variable that the amounts of food required for any two days may not be the same, the "personal equation" being very large.

THE CLINICAL RESULTS FROM THE USE OF PROFESSOR KLEBS'S TUBERCULOCIDIN.

By KARL VON RUCK, M.D.,

ASHEVILLE, N. C.

It is still doubtful that an unbiassed hearing will be accorded to anyone who has anything at all favorable to record either from Koch's original tuberculin or from any of its modifications. Both by professional opinions, most frequently formed from general impressions derived from medical literature, and from meddlesome interference of the public press (engendering optimistic and pessimistic views in succession), the patients have been swayed from one extreme to another, and for some time past early-stage cases feared even the contact with a physician known to make use of tuberculin or its derivatives in his practice.

The class of patients who still desire its application are such who have so far advanced in their disease that death stares them in the face, and with such material little chance exists to demonstrate the value of any remedy.

I have heretofore expressed my views as to Koch's tuberculin in current medical literature, and I have nothing to add or to deduct from my statements, after eighteen months' experience with a great number and all stages and phases of pulmonary and laryngeal tuberculosis. I am absolutely satisfied that when the remedy is properly applied it is as free from danger as we could wish it to be; that it does exert a local stimulating effect upon tubercular lesions regardless of their seat, and that such an effect is beneficial and has appeared so in over ninety per cent. of all the cases who have received the remedy for a sufficient length of time at my hands. I do not say that ninety per cent. were cured by its use; indeed, the great majority of the cases treated were in an advanced stage, and a cure was out of the question before the treatment was undertaken.

I have, however, at least fourteen per cent., all early-stage cases, where, after a year, the apparent cure after cessation of treatment may now be said to be permanent. In these cases there have been no symptoms whatever since their discharge. Several cases have since suffered from la grippe, with pulmonary complications, and no relapse has occurred, and I consider this as severe a test as could be applied.

In twenty-two per cent., all advanced-stage cases, the disease has been arrested by the treatment, and the arrest, with absence of any active symptoms, with comfortable health, ability to attend to business, and in a number, with subsequent general improvement as to weight and strength, has continued a year or more.

While I have no doubt whatever that in these results the strict management in my institution, the favorable climate, and other means which were employed auxiliary to the tuberculin treatment have had a considerable share, yet I am equally free from doubt that the use of the tuberculin has had its influence (in many cases most obviously) in arriving at these results.

I can abide my time, for the profession must ultimately arrive at the truth. Unfortunately, my method of administration requires an amount of control, thorough understanding of the disease, and an absolute familiarity with physical diagnosis, which can be carried out only in an institution, and for the details of which I refer to my paper published in the *Medical News* for March 26, 1892. I emphatically protest, however, against comparisons of my claims and results with those published by observers, in whose hands the administration of tuberculin was, in my judgment, a misuse of the remedy, and whose occasional successes must be ascribed to chance or accident.

Owing to the prejudices created by the results of non-painstaking methods, often in cases where the remedy was contra-indicated, nearly always in excessive doses, as a rule in advanced stages, and never under critical control and watchfulness of the local effects produced by each dose, I have in my practice abstained from employing the remedy, unless at the positive request of patients, and then only when in my judgment there is still a reasonable hope of conferring benefit with it.

I have since a year ago watched with great interest the various modifications of tuberculin, and, satisfied that improvement in its preparation will eventually be made, I have made careful trials, particularly with the tuberculocidin prepared by Professor Klebs. Its great expense under the large doses employed was at first a hindrance to an extensive trial; recently it has been much reduced in price. I have used of this substance nearly three hundred thousand milligrammes upon twenty patients, in doses up to forty-five hundred milligrammes per day.

Without going into details of each individual case, I may say that, with the exception of two cases, they were in an advanced stage. I have seen no unfavorable influence whatever from its use, neither have I been able to observe any local effects, as is the case with Koch's tuberculin, whenever we carefully look for it.

So far as subjective or objective symptoms are concerned, it seems to make no difference whether we inject ten or one hundred milligrammes, or whether we increase from one thousand to two thousand milligrammes. Indeed, in my early experience with the remedy, I frequently suspected that Professor Klebs had not only removed the dangerous properties from the tuberculin, but that he had removed its remedial principle as well.

By subsequent observations it appeared that in 17 out of the 20 cases the cough and expectoration were diminished, the physical examination confirming this by disappearance of râles and ronchi; objectively the patients felt a greater freedom in breathing. The vital capacity increased in 11 cases, varying from ten to sixty cubic inches. In 14 cases there was material diminution of the solid constituents of the expectoration as well; it became more mucous and admixed with air. In 5 cases the expectoration was reduced to a minimum; in 2 it disappeared entirely together with the cough; these were the cases in a comparatively early stage. In 8 cases the pulse-rate was unmistakably diminished from ten to thirty beats per minute. In 17 cases the general condition of the patients was improved. Out of 5 cases who had marked fever, the temperature became normal in 3; reduced in 1; it was not influenced in 1 (far advanced with septic symptoms).

The most remarkable effect of the treatment with tuberculocidin was its effect upon the tubercle bacilli; and it was evident in every case treated. After the doses had reached five hundred to one thousand milligrammes, in a few cases even earlier, and between the second and third week of the treatment, there appeared in the sputum the form of tubercle bacilli known as "degeneration forms." They were broken up, appeared only partially stained, and frequently were indicated only by a faint outline with a few dots of stain, resembling cocci, unless the immersion lens was employed. Alongside of these well-formed bacilli were observed.

In almost every case comparison with a number of previously prepared specimens was possible, as they were pre-

served from all the weekly examinations made, and the difference was striking and unmistakable.

In four cases the bacilli entirely disappeared in the first course of twenty-eight injections, in all others the degeneration forms continued, and the number of bacilli was materially decreased.[1] This effect upon the bacilli occurred also in the three cases, in which no other favorable effect resulted; these cases were hopelessly advanced and received the remedy as a last resort at their urgent request.

In the four cases in which the bacilli disappeared entirely, they reappeared, well formed and stained in two, and disappeared upon a second series of twenty-one injections, again showing the degeneration forms under doses of five hundred milligrammes and upward when the remedy was resumed.

In the sixteen other cases the remedy was reapplied in two cases, and the behavior of the germs was similar as before, becoming this time greatly diminished in number, but have as yet not entirely disappeared. It remains to be seen what a third series of injections will accomplish for these two patients.

No such effects were observed in cases who did not receive the remedy, except in several who were being treated with Koch's tuberculin, and in these in a slighter degree. Similar observations have been made by me under Koch's tuberculin heretofore, and also in cases of arrested phthisis, apart from the administration of specific remedies. I have, however, never seen the change occur so rapidly and be so well marked.

In laryngeal and other visible tubercular ulceration (mouth and pharynx) there was not observed any reparative process, as we had witnessed in the same and other patients under Koch's original tuberculin.

Thus my experience stands to-day with the tuberculin treatment in its original as well as modified form. The latter seems more particularly to have a germicidal effect, and in that respect my limited observations confirm the claims of Professor Klebs. I believe, however, that the local stimulating effect of the original tuberculin is of the greatest value in the repair of tubercular lesions, and an intelligent combination of this with the germicidal properties of tuberculocidin would at the present time hold out the best prospects.

Both remedies can be given to the entire avoidance of any untoward effect, and the worst that could happen to the patient would be, that, alone or combined, they should prove ineffectual in producing lasting benefit. Their use will in no wise hinder the employment of climate and other rational means; their benefit, as well as that of all other means, must of necessity be only temporary, or entirely unavailiug in the far advanced and last phases of pulmonary and laryngeal tuberculosis. In the earlier stages the results will be influenced the same as is the case with all therapeutic agents, by constitution, by the acuteness and virulency of the disease process, but also by correct management and intelligent use of remedies employed, and by the conduct of the patient undergoing treatment.

Galen's Hymn to the Creator.—In my opinion, true religion consists not so much in costly sacrifices and fragrant perfumes offered upon his altars, as in a thorough conviction impressed upon our own minds, and an endeavor to produce a similar impression upon the minds of others, of his unerring wisdom, his resistless power, and his all diffusive goodness. For his having arranged everything in that order and disposition which are best calculated to distribute his favors to all his works is a manifest proof of his goodness which calls loudly for our hymns and praises. His having found the means necessary for the establishment and preservation of this beautiful order and disposition is as incontestable a proof of his wisdom as his having done whatever he pleased is of his omnipotence.—*Pettigrew's Medical Biographies.*

[1] Gaffky's method.

APPLICATION OF ANTISEPSIS IN OPHTHALMIC AND AURAL SURGERY.[1]

By MATTHIAS L. FOSTER, M.D.,

ASSISTANT SURGEON MANHATTAN EYE AND EAR HOSPITAL, LECTURER AT THE NEW YORK POLYCLINIC, OPHTHALMOLOGIST TO THE LADIES' DEBORAH NURSERY AND CHILD'S PROTECTORY, AND TO THE UNITED HEBREW CHARITIES, LECTURER ON DISEASES OF THE EYE AND EAR AT THE H. W. BISHOP TRAINING SCHOOL FOR NURSES.

Much of the wordy discussion on this subject, which leads to no definite result except the mystification, confusion, and disheartenment of those who look up to the disputants as their teachers, would be avoided if the latter would take the trouble to ascertain the definition of two words which they use so freely, and regarding which they dispute so loudly—antisepsis and asepsis. So allow me at the commencement of this paper to refer to three leading medical dictionaries of to-day in order that a firm foundation may be obtained upon which to base our discussion. The dictionaries which I have selected as representing and embodying the use of the best medical writers of the present day are "The New Sydenham Society's Lexicon," now being issued by the New Sydenham Society, London; "The National Medical Dictionary," lately issued by Lea Brothers, Philadelphia, and the "Illustrated Encyclopædic Medical Dictionary," now being issued by Daniel Appleton & Co., New York. In the first-mentioned, the "New Sydenham Society's Lexicon," the nouns antisepsis and asepsis have been omitted, so we are obliged to turn to the corresponding adjectives to obtain a definition. Antisepsic is defined "having power to prevent putrefaction;" asepsic is "not liable to putrefy." In the "National Medical Dictionary" the definition of antisepsis is subject to criticism on account of the number of cross-references which are always to a certain degree confusing, and should be avoided whenever possible. It is "use of antiseptics; condition produced by them." Antiseptic is defined as an adjective, "opposed to putrefaction; preventing growth of organisms producing putrefaction;" as a noun, "an agent possessing such power." Asepsis is defined "absence of septic poisoning." In the "Encyclopædic Medical Dictionary" the definition of antisepsis is, "a collective name for measures intended to prevent putrefaction or infection with septic material." That of asepsis is, "freedom from putrefaction or from its effects." These definitions from these authorities do not appear to me to conflict, and I shall adopt the last-quoted definition of antisepsis as the more concise and definite. If you will allow me I will repeat it: "A collective name for measures intended to prevent putrefaction or infection with septic material." According to these definitions I wish you to note that antisepsis does not necessarily mean the use of carbolic acid, corrosive sublimate, or other powerful germicide, and that asepsis is a condition, simply a condition which in a wound or in tissues exposed to septic influences can be maintained only by measures which will fall under the definition of antisepsis.

It has not been many months since I heard a gentleman, eminent in ophthalmological circles, declare that he had never become a convert to the active local antiseptic measures practised in many of the clinics, but he had become more and more careful as to the cleansing of the eye, the previous treatment of any conjunctival or lachrymal catarrh, the cleansing of the instruments, and of the hands of the operator and of his assistants. He cleanses the eye with a solution of boric acid, uses hot water and soap for the instruments, dips them in boiling water just before using, and looks after the forceps with a magnifying glass. Now what is all this preparation for unless it is to "prevent putrefaction or infection with septic material?" But if this is the purpose, this is antisepsis. Perhaps the gentleman I refer to does not call it by this name because he does not employ a powerful germicide to produce the desired result. Possibly he may call it asepsis. I have heard it called so. But asepsis is a con-

[1] Read before the Medical Society of the County of New York, September 28, 1891.

dition of absence of sepsis. It is the condition aimed at by the measures he adopts, it is not the name of the measures.

The precautions necessary to combat the tendency to suppuration vary to a certain extent in different parts of the body. The surgery of the peritoneal cavity is very dissimilar from bone surgery, yet I have heard an eminent aural surgeon speak slightingly of the use of germicides in cases of operation for mastoiditis because such use has not been found necessary in laparotomies. Is there any point of similarity between the conditions in these two operations except that in each an incision is made through the skin and muscular tissue? The laparotomist opens into a cavity lined by a highly absorbent membrane, instinct to a high degree with the phenomena of life, and seldom in a suppurative condition. Experience has demonstrated the danger of absorption of poisonous substances by the peritoneum, and the safety found in comparatively mild, though efficient, precautions. None of these conditions are found in mastoiditis. The tissues differ as bone differs from peritoneum, and a suppurative inflammation is usually present. I do not know a single general surgeon accustomed to operate on bony tissues who would be content to open an abscess in a bone with less antiseptic precautions than those afforded by powerful germicides. The precautions which are thoroughly and sufficiently antiseptic in the one case are insufficient and incompetent in the other.

There is a vast amount of superstition in many minds associated with this same antisepsis. In the ranks of those who profess themselves to be unbelievers, as well as among the believers, are many who fail to grasp the true meaning of the word, who seem to consider the germicide a magic charm by whose catalytic action a miracle is to be wrought, suppuration prevented, and immediate healing induced. Such blind reliance naturally results in the neglect of other precautions, and, inevitably, bad results. The failures of enthusiasts and the sneers of the critics who belong to this class exhibit simply their own lack of understanding. But traces of a superstitious regard peep out occasionally where we least expect to find them. The ophthalmologist whom I have quoted as declaring that he had not become a convert to certain local antiseptic measures, cleansed the eye before operation with a solution of boric acid. I do not suppose that he used the boric acid to obtain its soothing influence on an eye already cocainized; he was not obliged to use it, for he could have used pure warm water instead, so I am unable to account for his use of the drug except on the ground of a slight yielding to a germicidal doctrine which he seems to oppose.

This class of critic is repelled by the tendency of genuine enthusiasts, whom he is obliged to respect, to go to extremes, to employ measures the value of which they cannot satisfactorily explain. For example, some years ago I became mildly sceptical regarding the antiseptic value of iodoform, while persuaded that it tended to allay the pain resulting from a wound, and asked one of the best general surgeons it has ever been my good fortune to know, whether he used iodoform in his dressings as an analgesic or as an antiseptic. With a marked degree of surprise he answered, "As an antiseptic." After a little conversation in which I remarked that, although I had seen him use it daily for months, I had never seen him use it except when supplemented by corrosive sublimate to such a degree as to render it impossible to determine whether it was of antiseptic value or not, he said that he used it because he felt safer when he did so, although he could not positively say that its presence was necessary to prevent suppuration. On another occasion I asked the same gentleman why he boiled his instruments to such an extent as to injure the edge of the knives and scissors. His reply was that perhaps they were boiled longer than was necessary, but he knew that they were safe. Such answers are not calculated to dispel doubt, but rather to impel its extension to other parts of the adopted procedure, and then, by a hasty generalization, to the method itself. Practical experience has proven the method right, the error, if any, to be in the overdoing of minor details. The ophthalmic surgeon requires equally as aseptic instruments as the general surgeon, but the edge of his knife must be superlatively keen. To render them aseptic he agrees with the general surgeon in the use of boiling water, but he finds that it is not necessary in order to obtain asepsis to carry the action of the hot water to the point of decomposition of the metal. A Graefe knife plunged for one minute in boiling water is rendered aseptic, but is not dulled by the casting off of minute particles of steel from its edge, as it will be if kept in the same boiling water a considerable length of time.

Apropos of the sterilization of instruments, the ophthalmic surgeon enjoys the advantage, seldom granted any other, of being able to use his instruments direct from the boiling water. In any other branch of surgery an operation usually requires more time and more handling of instruments, so that a sterilized solution in which to keep them after boiling, and in which to cleanse them occasionally is required.

In general surgery at the present day the site of the proposed operation is subjected to a most searching application of various germicides. In many cases the skin is scrubbed hours before with soap and water, washed with a germicidal solution, and a protective dressing of sublimate gauze is applied. When this is removed on the operating-table a number of germicidal agents are employed to ferret out any lurking nidus of infection and complete the cleansing. This is right and proper. I would like to employ this preparation on every case of mastoiditis, but the ophthalmic surgeon cannot adopt this means, for a single good and sufficient reason, the eye will not tolerate it. Germicidal solutions sufficiently weak to be tolerated in the healthy eye are so weak as to cause a reasonable doubt as to their efficiency. But the eye enjoys the advantage of a continuous irrigation with an aseptic saline solution, and the temporary irrigation which elsewhere is the principal antiseptic means can here act solely as an adjuvant to the antisepsis which Nature has provided. The lachrymal fluid is able to maintain asepsis in an aseptic wound of the conjunctiva or cornea, but is not able to neutralize the effects of septic poison introduced by the finger or instrument of the operator. The general surgeon does not find the ability to neutralize such effects in the powerful germicidal solutions which he employs, and the addition of a weak solution cannot be expected to result in the development of such ability. From these facts we may perhaps deduce an explanation of the great variance in the opinons of eminent ophthalmic surgeons regarding the value of these solutions. My own opinion is this, that while the addition of a weak germicidal solution may not be absolutely necessary, it is the addition of a contributive factor to the safety of the eye and should not needlessly be omitted.

Inasmuch as in every large eye-clinic a number of cases of acute trachoma, dacryo-cystitis, and other infectious diseases will be seen every day, and as the removal of the infection communicated by these diseases to the fingers of the surgeon cannot be guaranteed by the use of soap and water, measures should be taken to guard against possibility of infection from this source. The hands of the operator and of his assistants should be thoroughly scrubbed with soap and hot water, and then plunged for at least thirty sconds in a 1 to 1,000 solution of corrosive sublimate or other powerful germicidal solution. No one should be allowed to touch the face of the patient, or an instrument, who has not thus cleansed his hands. In no other way can danger of infection from this source be avoided.

The instrument should be plunged in boiling water for about a minute and should never be wiped. It is preferable for the surgeon to take them himself from the boiling water as he needs them.

The integument of the lids and of the neighboring por-

tion of the face should be thoroughly scrubbed with soap and hot water, and may then be bathed with a germicidal solution. While the latter cannot be said to be absolutely necessary it certainly adds another contributive factor to safety. The conjunctiva should then be bathed with the chosen solution at a temperature somewhat above blood heat. If a septic inflammation be already present in the eye, the germicidal solution should be as strong as can be well tolerated. After the operation the eye should be again bathed, the lids closed, and the integument again washed with warm water. If any drops, as of atropine or eserine, are instilled the solution used should have been rendered aseptic.

Repair proceeds rapidly in the eye, and the lids when closed form an almost complete protection, so the form of dressing is not of so great importance as in some other branches of surgery. The firm application of a pad of absorbent cotton to maintain the closure of the lids is usually sufficient. After certain operations, as for squint, it is not desirable to keep the eye closed, and in these cases a soothing lotion, feebly antiseptic in character, such as a solution of boric acid, salt and water, or a very weak solution of bichloride of mercury, is usually prescribed, but it seems doubtful whether the value of such solutions is due to their germicidal power.

In septic inflammations of the eye another problem confronts us. The suppurative process is established and must be checked. Germicidal solutions are positively indicated, as strong as can be tolerated, with which to cleanse the eye, retards the process, and so assist nature to cast off the pathological condition.

There is no superstition in these precautions, and any man who ascribes their observance to that source fails to apprehend their purpose and should never adopt any portion of them as a sop to superstitious prejudice. He is in honor bound as a reasonable man to neglect them all.

Operations on the eye and on the ear should be performed with equally efficient antiseptic precautions, but the technique of these precautions must necessarily differ very much. In the eye operations are usually performed on tissues which are not in a septic or suppurative condition, which are continuously irrigated with an antiseptic solution, and can be protected against infection after operation by simple means. In the ear, on the contrary, most operations are performed upon tissues already septic and incapable of being perfectly cleansed, or rendered proof against infection. The problem in the one case is usually to prevent infection of uninfected tissue easily protected, in the other to remove infection from tissue difficult to protect. The ophthalmologist may perhaps learn much from the laparotomist, but the aural surgeon should rather study the teachings of bone surgery.

How to cleanse the middle ear thoroughly is a problem which has taxed, and will continue to tax, the ingenuity of aural surgeons, and I believe I am right when I say that the practical application of antisepsis to the tympanum antedates the advent of the name. As thorough removal as possible of the products of inflammation and introduction of a powerful germicide, like sulphate of zinc or nitrate of silver, into the suppurating cavity, is essentially antiseptic treatment, and that has certainly been a recognized mode of treatment for at least fifty years. This is very possibly the reason why the advent of antisepsis caused so little change in the treatment of ear diseases. The advance had already been made, at least to a certain point.

Inflammation of the temporal bone differs from inflammation of other bones only in the difficulty of access to any part except the mastoid, in its dangerous contiguity to the brain, and in its importance as containing the organ of hearing. It is the bone of the body which demands the most careful treatment when inflamed, and at the same time is probably the bone which is most subject to inflammation. Every fact in the treatment of bone disease elsewhere demands the attention of the aural surgeon. The antiseptic problems to be solved are those common to all bone inflammation. They are to obtain free drainage, cleansing, retardation of the suppurative process, and protection. In suppurative inflammation of the middle ear it is necessary to employ the drainage Nature furnishes, through the external auditory meatus and the Eustachian tube, and the same means of access must be employed for the purpose of cleansing. Germicides are needed here for the same reason that they are useful in suppuration elsewhere, they serve to restrain the pathological process and so help Nature master the disease. The surgeon may be said to be dealing with an abscess in the petrous portion of the temporal bone, with openings for access and drainage ready made. One of these openings leads to the throat, and the danger of additional infection through this channel cannot be guarded against. But it is possible to guard the other opening, the external auditory meatus, with an absorbent dressing, after the custom of the general surgeon in the treatment of similar troubles elsewhere. That such a dressing is not customary, that it would not guard against all sources of infection, and that many patients finally get well without such protection, are utterly insufficient reasons why such a dressing, which has proven so efficient in the surgery of other parts of the body, should not be employed. The beneficial results obtained from the use of boric acid in cases of chronic suppuration with but a small amount of discharge, I am inclined to attribute to its action as an aseptic and antiseptic protective dressing to the inflamed region, preventing the access of more infection through the external canal.

In the mastoid portion of the temporal bone we have a better opportunity to avail ourselves of the technique of the general surgeon. I believe that everyone accustomed to bone surgery will agree that an abscess in a bone is best treated by an incision made, with due precaution against septic infection from without, through the periosteum, perforation of the bone at the most dependent part of the abscess, removal of any loose fragments of dead bone, cleansing of the cavity with a germicidal solution, the maintenance of drainage from the lowermost part of the abscess, and the application of a dressing which will absorb the discharge and at the same time guard the wound against external infection. The same antiseptic precautions should be taken in mastoiditis which have been found valuable in similar inflammation in other bones. The hair about the mastoid should be shaved for at least two inches from the site of the incision. The integument should be thoroughly scrubbed with soap and hot water, and then bathed with a powerful germicide. The ear should be perfectly cleansed and the remaining hair of the patient should be covered with towels wet with a powerful germicide and kept completely away from the hands of the operator. The hands of the operator and of his assistants should undergo the thorough cleansing I have described, the instruments should be sterilized in the same manner and should then be placed in a five per cent. solution of carbolic acid, or some equally powerful solution which will not injure the steel. If pus is found in the mastoid cells an opening should be made in such a manner as to guarantee drainage from their most dependent portion. Caries and necrosis should be treated as in other bones. Sequestra which have become separated from the living bone should be removed, but those which are still adherent should not be interfered with, is a rule to which there are very few exceptions. The cavity should be thoroughly irrigated with a germicidal solution at a temperature above blood heat, never cold; patency of the external wound should be maintained and perfect drainage secured by means of an aseptic drainage-tube of suitable size, or by aseptic gauze carefully and correctly packed into the wound, or by a combination of these methods, and an absorbent, protective, antiseptic dressing applied. Careful attention should be paid to the temperature of the solution with which the abscess cavity is cleansed at the time of operation and at the periodical

dressing of the wound. The bone should be sedulously guarded against being chilled.

Under no circumstances of which I can conceive could I feel it justifiable to apply a poultice after this operation. A poultice is very useful in cases of localized inflammation associated with a high degree of tension and a corresponding amount of pain, in that it causes relaxation of the tissues, thus relieves the tension and pain, and favors more rapid determination of the course of the inflammation. But after the tension has been relieved by an incision there is no opportunity for such action. If applied after the incision has been made, the poultice acts to relax and weaken the surrounding tissues and encourage them also to break down in suppuration. The acknowledged object in former days was to encourage suppuration, under the supposition that the tissues surrounding an abscess were infiltrated with a virulent humor which should be drawn out. Later research has negatived this supposition, and experience has proven that an abscess will heal more kindly if not poulticed after the incision has been made. Further, its application renders nugatory all previous efforts to produce asepsis, or an approach thereto. It is no answer to this that the abscess is septic when opened. After an acute abscess has been opened every succeeding effort is to reduce the amount of sepsis present, to render the cavity as aseptic as possible. If we cannot obtain perfect asepsis after an operation on a bone abscess we can obtain a much less septic condition, and the removal of as much septic poisoning as possible is just so much assistance to Nature to master the pathological condition. Therefore I wish to take this opportunity to protest against the employment of poultices after operations on the mastoid as a relic of the days of uncleanliness in surgery, worse than useless, dangerous.

I feel convinced that with a more definite understanding of the meaning and principles of antisepsis, and with a better appreciation of the needful variations in the technique of its application in various parts of the body, the number of dissenters from the doctrine will grow less, the wordy discussions to which I have alluded will fail, or, rather, will be replaced by debates of practical value regarding the best antiseptic means to be employed in the various operations upon these two important organs. If I shall have contributed in the slightest degree to the bringing about of a better common understanding on this subject the purpose of this paper will have been fulfilled.

7 East Forty-First Street.

Folk Medicine in Russia.—*Slovo*, of Kiév, reports some curious instances of popular doctoring in South Russia. The rural dentist places his patient upon a little stool and examines him. If an upper tooth is to be pulled he performs the operation with a simple pair of tongs like that used by cobblers. But if a lower tooth is to be extracted the operation is more complicated. The tooth is tied very skilfully with a violin string. The other end of the string is fastened to a hook in the ceiling. Then the stool is removed with a jerk from beneath the patient, who falls, his tooth remaining on the string, sometimes with the flesh around it. Intermittent fever is cured either by live frogs or by fright. When the sickness breaks out the patient is made to carry about him as many live frogs as can be put in his clothes. If that treatment does not help the patient his fellow-villagers try to frighten him. The most popular method of doing that is known by the name of Likaniye. A crowd of men and women come into the house and raise a quarrel with the patient. They treat him to the loudest and most offensive terms of reproach. That naturally irritates him, and he answers in similar terms. The crowd takes offence at his rude expressions and resolves to lynch him. A rope is put around his neck and he is dragged about until he is insensible on account of fright. —*The Sun.*

Clinical Department.

A CASE OF SUPPURATIVE HEPATITIS.

By ANDREW M. MOORE, M.D.,

Surgeon U. S. Navy.

J. W. K——, seaman, U. S. N., aged forty-four years and eight months, native of Batimore, Md., was admitted to the Naval Hospital, Mare Island, Cal., October 24, 1891, for treatment. Hospital ticket accompanying him from United States Fish Commission Steamer Albatross, gave the following history: "Phthisis pneumonica acuta? Patient has enjoyed excellent health during the three years on this ship, until September 24th ult., when he was admitted to the sick list with colica, originating from exposure to cold in the hold of the ship. Was discharged to duty in six days. He again applied for treatment, October 15th, and stated that he had not felt well since October 3d. Upon admission to the list (October 15th), he was considerably emaciated, and his strength was much impaired; appetite very poor. Since that time he has lost flesh steadily. When admitted had temperature 100.6° F.; since then his temperature has been irregular, ranging from 99.8° F. to 103.8° F.; has had chills at irregular intervals, followed by vomiting. Has had tenderness over lower border of liver, and occasional headache. Bowels generally costive; urine normal No pain in chest, no cough or expectoration until two days ago; at present has increased vocal resonance over lower lobe of right lung, dulness on percussion, and a few moist râles."

On admission to hospital, temperature, 100° F.; pulse, 100; respiration, 30; tongue dry, and coated with brownish fur; breath, foul-smelling; slight cough with scant mucous sputum; respiratory murmur somewhat exaggerated in both lungs; crepitant râles and, at times, bronchial respiration over lower lobe of right lung posteriorly and laterally; has no pain, but there is slight tenderness in the right hypochondriac; area of liver-dulness normal; normal resonance in abdominal region and deep pressure here fails to elicit any tenderness; ingesta provokes emesis without producing gastric pain; food vomited has odor and taste (subjective) of fermentation of putrefaction; adynamia and noticeable emaciation. Ordered pepsin and dilute hydrochloric acid t. i. d., and to have a diet of warm milk.

October 25th (day after admission).—Temperature, A.M., 98.4° F.; pulse, 86; respiration, 28; tongue still heavily furred but moist; odor of breath less offensive; the patient slept soundly (first time for two weeks), and says he feels better; warm milk retained.

October 30th.—The patient has had chills, with vomiting and fever, nearly every day. There is tenderness over the hepatic region, and as this has persisted, an exploring needle (long hypodermic) was introduced about three inches into right lobe of liver at seventh intercostal interspace, on a line with the nipple, in the hope of finding an abscess, but without success; the exploration was made under antiseptic precautions, and, the parts punctured having been anæsthetized by subcutaneous injection of a four per cent. solution of cocaine, the suffering produced was insignificant.

November 2d.—No chill or emesis since October 30th. Temperature, last night, 98° F.; this A.M., 102.2° F.; pulse, 102; respiration, 30; tongue coated and moist; breath offensive; to have liq. sodii chlorinata, 1 to 8, as a deodorizing mouth-wash. Treatment by quinia and milk continued.

November 13th.—The temperature was normal for several days, but yesterday there was a chill preceded by vomiting at 2.30 P.M., with temperature, 104° F.; temperature at 9 P.M., 99.2° F. This A.M. at 7, chill, with temperature, 103° F.; occasional coughing; no pain; no profuse perspiration during or after chills.

November 14th.—Condition being unimproved, and

patient steadily growing weaker, another exploratory puncture was made with the hypodermic needle into the right lobe of the liver, to a depth of about three inches, at the eighth intercostal space, on a line with the posterior fold of the axilla, with the renewed hope of discovering a pus-cavity, and relieving the patient, but again without success; the exploration, which was made after the same preliminary preparation as in the operation heretofore detailed, was attended with but little pain, and in neither case was there the slightest appreciable resultant harm. At the autopsy, several weeks subsequently, a careful examination failed to discover any trace of the needle's path.

November 25th.—The patient has a chill every day at a different hour, with a great excursion of the temperature curve, at times as much as 8° in a few hours. He is apparently growing weaker, is much emaciated, and quite despondent, but uncomplaining, except of the weakness and the tediousness of confinement to bed.

December 9th.—About 5 P.M. yesterday, the patient was attacked with pain on coughing and on deep inspiration over the lower lobe of the right lung and in the hepatic region; examination this A.M. reveals pleuritic friction sound over the part of the lung indicated, and physical signs point to effusion into the right pleural cavity posteriorly; there is also distinct, though not very marked, swelling and œdema at right hypochondria and right side of the epigastrium, in which region there is decided tenderness on pressure, but no fluctuation can be made out. Ordered cataplasms of linseed meal.

December 29th.—The patient had a severe chill last night, and is very weak this A.M.; temperature, 98° F.; pulse, 95; respiration, 36. On account of the extreme weakness a careful examination of thorax has not been attempted, but, with exception of signs of liquid in right pleura and diminished respiratory murmur and some râles at the base of the right lung, the result of such examination as has been undertaken was negative.

January 8th.—The patient died from exhaustion to day.

Autopsy, seven hours after death. Rigor mortis, extreme emaciation, face and general cutaneous surface livid; liver *in situ*, not extending beyond normal limits, color and contour normal, weight three and one half pounds. An abscess was found in extreme right end of the right lobe, irregularly spherical, the size of an orange; about one inch of hepatic tissue intervened between its cavity and the diaphragm, at which point the liver, somewhat swollen, was strongly adherent; the pus was creamy, apparently laudable, and the cavity was lined with a pyogenic membrane; the gall-cyst was distended with a thin greenish yellow fluid, with floating granular matter, amount estimated at four ounces. Other abdominal organs exhibited no appreciable pathological condition; heart and great blood-vessels normal; right pleura adherent to the lung, diaphragm, and thoracic wall, and contained one pint (estimated) of sero-purulent fluid; right lung œdematous throughout, grayish in color, adherent to the diaphragm, and contained three small abscesses, all located in the lower lobe. There was also some sero-purulent matter in the air-vesicles and bronchioles of the lower lobe. The left pleura was non-adherent, no effusion; lung œdematous, the lower lobe being in the stage of red hepatization, and containing four metastatic abscesses of small size.

This clinical record illustrates the difficulties which lie in the way of a correct diagnosis of suppurative hepatitis where the local symptoms are obscure, and may prove of use to others who may be confronted with similar cases. During the course of the disease there was a continual recurrence of the question, Is it hepatic abscess, septicæmia, or the intermittent form of acute miliary tuberculosis? As regards the first, the local signs and symptoms—obscure and inconstant pain and tenderness, and the absence of swelling and of increased area of hepatic dulness, were not sufficiently pronounced to insure a definitely affirmative answer, though the treatment was based upon this theory. As to septicæmia, a careful search and inquiry failed to show any septic origin, no wound, disease of bones, hemorrhoids or other intestinal lesion, and cases of so-called spontaneous origin are rare and of short duration. Finally the theory of acute miliary tuberculosis was discredited, though not entirely abandoned as a possibility, on account of the comparatively infrequent respiration, about thirty per minute.

It is a reasonable theory that the "colica" from which the patient suffered a few weeks before admission to the sick list with his final illness, and since which, apparently, he had never been quite well, was due to indigestion, and that some peccant product of this mal-digestion was carried by a branch of the portal vein into the right lobe of the liver, where it set up an insidious (as far as the local symptoms were concerned) suppurative inflammation; that this inflammation by contiguity excited a localized pleuritis and pneumonitis at the base of right lung; that eventually septic material was carried by the hepatic veins through the right side of the heart to the lungs, producing metastatic abscesses on both sides, and, in addition, empyema on the right. If this is the true explanation, there was a good chance that the patient's life might have been saved, if the abscess could have been located in time and aspirated. Unfortunately there was doubtful evidence as to its existence, and no indication as to its seat; and the two explorations were made with no other guide to the judgment than the knowledge derived from statistics that the right lobe is much more frequently the seat of suppuration than the left. It is possible that another exploration, which was proposed, might have found it, but, as the patient objected, it was thought best, under the circumstances of his weak and nervous condition and the absence of definite indications, not to insist upon it.

The case is instructive, also, in confirming experience as to the harmlessness of aspirating the liver under proper precautions, as well as in pointing out the value as an aid to diagnosis in cases of hepatic abscess with obscure symptoms, although it was of no assistance in the present instance. The obscurity and incompleteness of the local symptoms were probably due to the fact that the abscess was not very large, that it was deep-seated, and that it made slow progress toward the surface.

SOME PERSONAL OBSERVATIONS UPON A CASE OF FRACTURE OF THE SPINAL COLUMN.

By JOSEPH N. STUDY, M.D.,

CAMBRIDGE CITY, IND.

On Friday evening, August 30th, during the performance of a circus, W. L——, aged nineteen, whose general physique was seemingly almost perfect, whose occupation was that of chief tumbler in a circus, was in the act of turning a double somersault. The feat is said to be one that few men attempt to perform, and is accomplished by running and jumping from a spring-board into the air, the body being flexed to an extreme degree, and assuming as near as possible a circular shape, and going with great velocity, turning twice, alighting upon the feet upon a thick straw mattress.

In the act, the second turn was nearly completed, the performer alighting upon the mattress with his shoulders and back instead of his feet. The act was closely observed by the writer, as well as several hundred people. Paralysis was instant and absolutely complete, both motor and sensory, from the lower part of the neck, and never was there any return of either sensation or motion till death, which occurred on the twelfth day. Priapism was instantly present, and remained constant till a short period before death. The bowels and bladder were paralyzed, breathing diaphragmatic and labored. Pain quite severe when pressure was made over the fifth cervical vertebra, and any movement of the head was attended with severe pain. Careful examination failed to

detect either deformity or crepitation. Neither was there any bruising or discoloration of the parts. His temperature was taken three times a day, and upon several times registered 106° F., 106¾° F., and 107 F., in the axilla. His urine was drawn by catheter, and on different occasions measured from six to eight pints in twenty-four hours. His appetite was excellent, and he relished even in large quantities all kinds of food, and drank enormous quantities of ice-water. Mind bright till a short period before death.

Circumstances were such that his friends deemed it best to remove the patient to a hospital one hundred and fifty miles distant, which journey was made in an express car, and was seemingly accomplished without detriment to the patient. Eight hours after entering the hospital the man became unconscious and soon expired. No autopsy was made.

Cases of fracture of the spine from muscular contraction have been reported, but in most cases with considerable doubt. In the above case my diagnosis was one of fracture of the fifth cervical vertebra; all symptoms pointed to such an injury.

Considering the extreme flexed condition of the spinal column, attended with powerful muscular contraction, and the small resisting body upon which the man fell, it would not seem incredible to believe that muscular contraction was largely the cause of the injury.

A CASE OF CHILDBIRTH COMPLICATED BY FACIAL ERYSIPELAS.

By W. B. VANDERPOEL, M.D.,

NEW YORK.

Mrs. K——, primipara, was seen January 28, 1892. Was suffering from a swelling of the right nostril and cheek, evidently erysipelatous; had for a few days before complained of general malaise and of an acute coryza, the latter probably furnishing the starting-point for her present trouble. Temperature, 101° F.; pulse, 100. She was between eight and nine months pregnant. I ordered phenacetin, gr. v., every two hours; sweet spirits of nitre, ʒ j., every four hours, and lead and opium wash.

January 29th. — Temperature, 102° F.; pulse, 100. Erysipelas has extended to the neck.

January 30th.—Temperature, 102° F.; pulse, 110. The erysipelas involves both cheeks and forehead, the eyes are almost closed, and the eyeballs are injected and irritated. I ordered boric acid lotion for them, the other treatment being continued.

January 31st.—The woman was taken with labor pains at 4 A.M., the child being born at 11 A.M. There was only slight laceration. The mother's general condition had improved, the face being less swollen. Temperature, at noon, was 99° F., at 4.15 P.M., 102½° F., and at 8 P.M., 103° F. A carbolized douche was used. The child was removed from the room and its umbilicus was dressed with iodoform gauze.

February 2d, 9 A.M.—Temperature, 102° F.; pulse, 98. Peptonized milk was the only thing retained in the way of nourishment. Dr. D. M. Stimson was consulted and approved of my treatment.

February 3d.—Temperature, 100° F.; pulse, 86. The vaginal douche is given three times daily.

February 6th, 9 A.M.—Temperature, 102½° F.; pulse, 98. Lochial discharge is offensive and dark-colored. By advice of Dr. Stimson I gave an intra-uterine injection with Chamberlin's tube, using a two and a half per cent. solution of carbolic acid.

February 9th, 8 P.M.—Temperature, 101° F.; pulse, 92. The intra-uterine douche was used only once daily for the next three days, and then discontinued.

February 13th.—The patient sat up and rapidly convalesced.

On February 18th a child in the same house, but on a different floor, in spite of all care on part of attendants, developed redness on the right side of the neck. Temperature, 102½° F.; pulse, 120. I ordered lead and opium wash, diluted one-half.

February 19th.—Temperature, 102½° F.; pulse, 140. Erysipelas spreading.

February 20th.—Temperature, 101½° F., and later 99½° F. There is a tendency to collapse. Whiskey was ordered. The erysipelas now involves all the back of the neck, left shoulder and breast, and extends down the back to and including the left buttock. The child died at 3 A.M., February 21st.

The main point of interest was that the umbilicus, although not all healed, remained free from inflammation. It had been washed daily with a solution of bichloride of mercury, and dressed with iodoform gauze.

SCARLET FEVER FOLLOWED BY TYPHOID FEVER.

By CARL D. S. FRÜH, M.D.,

PHILADELPHIA, PA.

Lulu W——, in the early part of 1889, was taken ill with scarlet fever, lasting nine days. There was no vomiting at the onset, no sore throat whatever, a temperature of 104° F. and 105° F. lasting the nine days, when a slight scaling was noticed from the left shoulder-blade.

On the tenth day, Robbie W——, aged four years (brother), was taken with a typical case of scarlet fever. Recovery took place without any special features to note.

Lulu lingered, very feeble, and did not seem to improve; when, in the third week, another chill took place, this ushered in an attack of typhoid fever. It ran a course of four weeks. Two years later, in 1891, the child was taken by an aunt to an adjoining State; scarlet fever had been in the house, three of her cousins having been ill. She was allowed to remain, and two weeks from her entry to the house she was again taken ill with this disease, this time with all the symptoms marked; desquamation was excessive; this was again followed by an attack of typhoid fever with exceedingly grave symptoms, hemorrhage lasting forty-eight hours, extreme conditions of collapse, and finally a greatly protracted recovery.

Robbie also had another attack of scarlet fever, marked in the symptoms, quite as distinct as the first attack; he also followed with typhoid fever, but being of a robust type, recovered from both conditions very promptly.

The mother, aged twenty-eight years, was ill with typhoid fever during February and March of 1892.

We have then scarlet fever and typhoid fever twice within two years, one disease following the other in the same individual, Lulu W——.

One attack of scarlet fever followed in two years by another attack of scarlet fever, and then by typhoid fever, in Robbie W——.

Brom-Æthyl Narcosis. — Gleich recalled his former communication on this subject and said that the experiments with this drug had now been used in Professor Billroth's Klinik three hundred times without a single case of death. Unhappily, however, one death has resulted recently in the ambulatorium (out-patient department) that deserves careful attention. The patient had a large carbuncle on the upper part of arm that was considered suitable for cutting. He was brought under the influence of brom æthyl, but suddenly became cyanotic, respiration and pulsation immediately ceased; artificial respiration was kept up for one hour and a half, but without success. Professor Hofmann recorded the following in his post-mortem: Both lungs were adhering to the pleura; cardiac tissue distinctly fatty and friable; the microscope confirmed parenchyatose degeneration of heart, liver, and kidneys. The brain, however, was not hyperæmic, which is the opposite to that found in chloroform deaths. These results led to the conclusion that any narcotic would have proved fatal.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 43, 45 & 47 East Tenth Street.

New York, June 18, 1892.

THE MIXED LICHEN GROUP.

LICHEN, though one of the oldest terms employed in the nomenclature of skin diseases, is still a much-confused designation. Lichen simplex of the older writers no longer exists to-day; not that this form of lichen has passed away, but its name has. Cases are still seen, but they are now called papular eczema.

Lichen scrofulosus, consisting, according to Hebra, in millet-seed-sized pale yellowish or brownish elevations, situated mostly over the abdomen, chest, and back, has been looked upon by Tilbury Fox as simply a pityriasis pilaris in a scrofulous subject, and not a true lichen. The disease is extremely rare in this country, many dermatologists even never having encountered it here.

Hallopeau finds it equally rare in France, but believes it is almost always accompanied by tuberculous lesions. It has been observed to begin near tuberculous nodules in which bacilli have been found, and which injections of the Koch lymph have caused to disappear.

This author regards lichen scrofulosorum as due to a localization of tuberculosis, in subjects predisposed to it, within the pilo-sebaceous follicles, which under its influence take on a special mode of action. This predisposition is met with exclusively in young subjects.

Lichen tropicus is a term applied to the condition usually known as prickly heat. It is very common in New York, as in many other non-tropical places, especially in the summer time, and the name is misleading in another sense, for the lesions are quite as often vesicular or urticarial as they are purely papular, which they should always be, primarily, to deserve the name lichen. It would be more appropriate and less confusing to do away with the name lichen tropicus, so much employed, and substitute for it one which would indicate that the disease belonged among the affections of the glandular apparatus of the skin.

Lichen circumscriptus, as applied to papules grouped together in elevated patches, increasing by circumferential enlargement, especially situated on the back of the forearm, hand, hips, and calves, has recently been considered by Vidal as a lichen simplex chronicus. This writer regards pruritis as the primary, and the papillary formation as a secondary product, and the whole process as a neurosis. He finds that patients usually present other nervous manifestations, and recommends constitutional treatment directed to the nervous system, while anti-pruritic and occlusive dressings are used externally.

Lichen ruber and lichen planus appear to be almost as much confused to-day as they were ten years ago. Three papers were read on the question of their identity at the American Dermatological Association in 1888, and it was thought at the time that the discussion which then took place had about settled the point of their being two distinct diseases. It has since transpired, however, that one of the cases reported can be classed as psorospermosis, and others then regarded as lichen ruber now go under the designation of pityriasis rubra pilaris, which the French claim was described by Devergie, and often confounded with lichen pilaris as well as with Hebra's lichen ruber. The whole question was discussed in the International Dermatological Congress held at Paris in 1889, and Kaposi maintained that Besnier's pityriasis rubra pilaris was identical with his lichen ruber acuminatus, and he thought two diseases alone should be called lichen:

1. Lichen ruber; of which there are two varieties, *acuminatus* and *planus*.

2. Lichen scrofulosorum.

Opposing this view, Hans Hebra regarded the lichen ruber described by his father as a severe and often fatal disease, not at all to be confounded with the more benign pityriasis rubra pilaris.

Dr. Minuti, of Florence, has made a recent study from which he concludes that lichen ruber of Hebra and lichen planus of Wilson are but two varieties of the same morbid process, and may co-exist in the same individual. The essential morbid process in lichen ruber consists in a true dermatitis of the papillary layer, having its origin in the blood-vessels, the alterations in the epidermis being secondary.

Lichen miliaris is still another form of papular eruption which requires consideration. At the present time it is in a not less confused state than are the other lichens. Lavergne has called it acute lichen planus, and Dubreuille holds the same view, while Robinson looks upon it as an acute papular eczema. It is characterized by an abundance of flat papules the size of a pin's head, some of which may enlarge and form little circles surrounding a depressed centre, but the isolated papules are always in great excess of these patches. There are a variety of papular eruptions occurring in children, which at some period of their evolution simulate this miliary lichen, but according to Dubreuille the diagnosis is rendered simple by the fact that in all these affections lesions of different age and nature exist at the same time, showing the eczematous, strophulous, or syphilitic nature of the eruption. It is much to be desired that an agreement should be reached by the dermatologists as to just what cases should be included under the term lichen, and how many varieties of the disease there really are.

THE QUESTION OF A FEE.

A RICH man living in Chicago had an only son who was taken very ill with a malignant form of diphtheria. He searched the city for the best skill to be obtained in treating such a malady medically and surgically. The desired person was found. The operation of intubation had to be performed; it was done, and the boy's life was saved. Time passed, and the doctor sent in a bill for

$2,000. The rich man thought this robbery. He made inquiries around the town, and found that intubation had been often done for a much less sum. He refused to pay; the doctor has brought suit, and the Chicago profession is lamenting that there should be a question about such a fee.

There can be no doubt among just minds that the service rendered was worth all that was charged for it. Because a surgeon performs a capital operation successfully and charges nothing, it does not follow that it was worth nothing; or if he charged but $50, it does not follow that this is the fair price. Many surgical and medical services cannot be estimated in money value. The trouble with our Chicago brethren is, perhaps, that they have in the past been estimating their work at too low a rate.

IMMUNITY.

Professors Brieger and Kitasato, and Dr. Wassermann, working in Koch's laboratory, have found a method of preparing a substance which confers immunity to animals from infective diseases such as typhoid, diphtheria, cholera, and tetanus. The bacilli of these diseases, with their culture fluids, are exposed to the action of extracts of thymus gland at a temperature of 65° to 80° C. This kills the bacilli, but leaves in the fluid an antitoxine which confers immunity.

Immunity seems to be secured rather easily and in various ways in experimental laboratories. What is wanted is something that works in practice. Recently Dr. G. Taruffi has reported a sixth case of tetanus cured by the antitoxine of Tizzoni and Cantani, and this has an encouraging look.

ARTIFICIAL SEA-SICKNESS.

Dr. Graily Hewett has succeeded (*British Medical Journal*) in producing a very good imitation of sea-sickness by means of a swing and an oscillating mirror, thus combining visual disturbance with rhythmical motion of the body. He found that in those who were "good sailors," and not in the habit of suffering from sea-sickness, there were no particular effects observed. In those who were in the habit of suffering from sea-sickness, marked discomfort was produced within ten minutes or a quarter of an hour, during which the swing and the mirror were both in motion.

The first discomfort felt was, in some cases, giddiness; in some, a fulness in the head; in some, headache; these discomforts being quickly followed by a rising in the throat, a catching in the throat, a feeling of sickness, or sensation of nausea, more or less pronounced. The exact effect differed in different cases, but the effects appeared to be always recognized as the initial symptoms of sea-sickness by the individual experimented upon. The rapidity with which these symptoms were produced varied; those who were most liable to sea-sickness were soon affected by the combined swing and mirror action. Two or three minutes sufficed in some cases to produce an unmistakable illness, and desire to discontinue the experiment. In some cases the mirror disturbance alone, and unassisted by the swing action, was sufficient to induce sensations like those of sea-sickness.

The motions which most quickly succeeded in producing a feeling of illness were, in a large number of cases, oblique oscillation of the mirror, associated with movement of the swing in an ovoid described in a vertical plane.

The downward motion in swinging seemed to be the most effective.

As regards treatment, Dr. Hewett found that the fixing of the eyes at a distance, or upon the sky, or better, simply bandaging them, would often keep off sea-sickness. Lying on the back still further helps this, as long experience has shown.

PREVENTING BLINDNESS.

An Act for the prevention of blindness has just been made a law by the Rhode Island Legislature. It is similar to the New York State law, and Rhode Island is the first New England State to adopt it. The important paragraph is the first, and it reads as follows:

"Should any midwife or nurse, or person acting as nurse, having charge of an infant in this State, notice that one or both eyes of such infant are inflamed or reddened at any time within two weeks after its birth, it shall be the duty of such midwife or nurse, or person acting as nurse, so having charge of such infant, to report the fact in writing within six hours to the health officer, or some qualified practitioner of medicine, of the city or town in which the parents of the infant reside."

It has been called the "Sore eyes Bill." But as the sore-eyes in question cause ten per cent. of the cases of blindness, and is the largest single factor, it naturally deserves special, if not legislative, attention. We shall watch the results of the laws so far enacted with much interest, and trust they may prove effective.

When is a Man a Father?—Dr. W. B. West, of Fort Worth, Tex., writes: "Will you be so kind as to answer through your journal this question: 'When is a man a father?' I will state the question as it was presented to me. A lawyer of our town bet another that a friend of theirs who had just married would become a father in ten months. At the end of the ten months my friend called upon his friend for the bet, when he was informed that he had won the bet since the wife aborted at three months. Investigation proved this to be true. The question then arose, who had won. They could not agree and the medical men were called in. I took the ground that he could only be a father when the child had breathed; some as soon as the woman became pregnant. We have discussed this question several times, and I think are farther from the solution than ever. Can you not help your poor brothers down here in Texas?"

[A man is not a father until he has a child, and an abortion is not a child. The fact in such a case must take the place of an intention. We do not believe in betting on such ventures, but our gallant Texan brethren may have different views from ours on this point. We are sorry to say, however, that our correspondent has won.—Ed.]

For the Palpitations and Hot Flashes of the Climacteric, veratrum viride is highly recommended.

News of the Week.

American Medical Association.—At the final General Session of the Association, held on Friday morning, Dr. J. Berrien Lindsley, of Nashville, Tenn., delivered the address on State Medicine, taking for his subject, "The People and the Public Health Movement." He began by citing a number of instances of sanitary reform, here and in Great Britain, in which it was seen that the reform was inaugurated not so much by the medical profession as by the general public, looking at first to its protection from disastrous epidemics, and next to relief from preventable diseases and improvement in daily health. It may be looked upon as an outcropping of the well-defined tendency of the times toward the elevation of the people. But, though not a medical movement, yet from the knowledge required to put it forward, medical men were naturally from the start called in by its promoters, and they soon took the lead. This is especially true in America, where, in nearly every instance of city or State progress, physicians have been the pioneers. So much is this the case that there is now some danger of the public looking upon sanitation as belonging exclusively to our profession. No greater mistake can be made. For it is law, and not medicine, that is most concerned. The prevention of disease and its cure are two very different affairs. Medical science can dictate what kind of laws should be made for the promotion of the public health, but is powerless to enforce these laws. Here the people in their individual and collective capacity must act.

Dr. Lindsley then recounted the efforts made to organize a Medical Board of Health, and spoke of the good work it accomplished at the time of the yellow-fever epidemic in Memphis, in 1879. How it came to pass, he said, that after a few years, just sufficing to prove its great capacity for good, it was starved to death, no one has satisfactorily explained. Perhaps it was owing to the fact of not being in the usual model of government offices at Washington. Had it been a bureau in the Department of the Interior, those familiar with Washington hold that it would now be in existence, and in a fair way to become a department, with or without a seat in the Cabinet. He told of the evolution of the Department of Agriculture from an insignificant branch of the Patent Office, itself a bureau in the Department of the Interior, to a department with its head a Cabinet officer, and expressed the belief that, sooner or later, a Department of Public Health will exist as a part of the national government. Among the bureaus in this department should be those of maritime quarantine, vital statistics, topographical survey, Marine Hospital Service, Medical Library, and scientific research. These matters are all attended to now by the general government under different departments, and in a disjointed and more or less imperfect manner, but their prosecution should be brought together under one responsible head. The elimination of all these offices from the departments now looking after them, in order to make up a great Department of Public Health, can take place with no injury, but rather a relief, to the present secretaries. The over-burdened Treasury Department can readily spare the United States Marine Hospital and Coast Survey. So can that of the Interior the Census Office and the Geological Survey. War has ample scope and verge enough without the Medical Library, as has the Navy without the Museum of Hygiene.

At the conclusion of Dr. Lindsley's address the usual vote of thanks was passed to the citizens and profession of Detroit, and to all who had extended courtesies to the Association, its delegates, and visiting ladies. The retiring President expressed his appreciation of the kindness and assistance he had received from the members, and then introduced the new President, Dr. Hunter McGuire, of Richmond, Va., who in a few words thanked the Association for the honor which he had received in being elected to preside at its next meeting. Dr. Fomento, President of the American Public Health Association, was then introduced and made a brief address, after which the Association was adjourned, to meet in Milwaukee in June, 1893.

Medical Legislation in New York.—This year a bill was introduced in the Senate, entitled "An Act to Incorporate the Bayard Homœopathic College and Dispensary." We suppose, says *The Post-Graduate*, the name Bayard is intended to be complimentary to the late distinguished homœopathic physician, Dr. Bayard. The doctor was a gentleman with very pronounced notions about homœopathic practice, and found himself latterly in very different therapeutical positions from so-called homœopathic practitioners of the State. Whether his friends have really anything to do with this bill, or whether it is merely an attempt to use his honored name for private purposes, we of course do not know. This proposed college was to graduate doctors of medicine after two years of study, and then their diplomas would be a license to practise throughout the State, without passing an examination from the State Board of Medical Examiners. There are other remarkable features of the bill. One requires that the college shall never teach anything but true homœopathy, which is defined in this ludicrous bill. If a more scrupulous or more intelligent class of men were sent in greater number to the Legislature, such wretched bills as these would never become laws.

A New Academician.—At their last meeting the members of the Académie des Sciences proceeded to fill up the vacancy in the Section of Medicine and Surgery caused by the demise of Professor Richet. There were three candidates—all surgeons—viz., Professor Guyon, Professor Lannelongue, well known as the inventor of the new sclerogenic treatment of tubercular and other affections, and Professor Duplay. Professor Guyon was elected by a small majority over M. Lannelongue.

The Milwaukee County Hospital.—The Milwaukee County Hospital is being investigated, and charges of mismanagement are being freely made. There is a general feeling that there has been a great deal of looseness in the management of the county hospital.—*Times and Register.*

The Woman's Pharmaceutical Association.— The Woman's Pharmaceutical Association of Illinois has been chartered, with Mrs. I. H. Roby, of Chicago, President; Mrs. Viola A. Griswold, of Chicago, Secretary; and Mrs. Cecilia Terril, of Chicago, Treasurer. Its objects, in the main, are to establish an organization of

female pharmacists, but as a secondary issue it will take in hand the matter of a woman's pharmaceutical exhibit at the World's Fair.

The Death of Dr. William R. Birdsall.—Inasmuch as by the death of Dr. William R. Birdsall, the New York Neurological Society has lost an active member, whose eminent services in our department of medicine have secured for him our highest respect, and whose many attractions of character and personality have awakened our warmest attachment; therefore,

Resolved, That we record upon our minutes this expression of our great sorrow at his untimely death; of our appreciation of his eminent ability, untiring industry, and scientific accuracy and skill; and of our tender regard for the many admirable qualities which will endear his memory to us for many years.

Resolved, That these resolutions be published in the current medical journals, and that a copy be sent as an expression of our deep sympathy to the afflicted family of our deceased friend.—M. Allen Starr, M.D., Charles L. Dana, M.D., Græme M. Hammond, M.D., *Committee of the Council.*

Dr. Charles A. Powers has been elected Attending Surgeon to the Cancer Hospital, to fill the vacancy created by the resignation of Dr. Hartley.

Dr. Gustave W. Bratenahl has been elected Assistant Gynecologist to the Cancer Hospital.

The Musical Anus.—A correspondent of the *Boston Medical and Surgical Journal* writes: "Your correspondent, K, refers to Dante's mention of a case of musical anus. I cannot compare the references now, but Montaigne, in one of his many essays interesting to medical men ("On the Force of Imagination"), gives the following: "St. Augustin (*de Civit. Dei*, xiv., 24, and the Comment. of Vives, *in loco*) speaks of having seen a man who could command his back trumpet to sound as often as he pleased, and Vives supports this statement with another example, in his time, of one who could do this in tune." The above seems to be of sufficient interest, pathological as well as literary, to be put on record."

Trinity Hospital.—Drs. Nelson H. Henry and Charles A. Powers have recently been appointed on the attending staff.

Owing to the death of its editor and publisher, Dr. J. Thacker, the *Medical News*, of Cincinnati, has been discontinued.

The San Francisco Polyclinic and Medical Department of the University of California have united.

Dr. R. W. Taylor has been appointed an Attending Surgeon to the Second Surgical Division of Bellevue Hospital, one ward (No. 10) of which is devoted to genito-urinary surgery and venereal cases.

Dr. Philip Donlin, Deputy Coroner of this city, and well known in medical and political circles, died last week.

The College of Physicians and Surgeons held its annual commencement on June 8th, and graduated a class of 116. The degree of LL.D. was conferred upon Dr. Fessenden N. Otis. Dr. T. Mitchell Prudden has been made Professor of Pathology. Dr. Robert F. Weir has been made Professor of Surgery, vice Dr. Charles McBurney, who has resigned.

Science and the Eight-Hour Movement.—In view of the recent May Day demonstration in support of "an eight-hour day," it may be interesting, says the *Lancet*, to recall the experiments by which Pettenkofer and Voit attempted to ascertain what amount of work a healthy laborer could accomplish without injury to his health. They constructed a chamber in glass which was hermetically closed. Inside they placed a wheel to which was attached a chain. By turning the wheel the chain raised a weight of twenty-five kilogrammes. A healthy, vigorous laborer was put inside this glass room; and, deducting the time required for meals, he was made to turn the wheel for nine hours a day. This was considered equivalent to hard physical work. The workman was carefully weighed before and after the experiment; the food supplied to him was likewise weighed and analyzed. Very great care was taken to make this glass room absolutely air-tight. No air could get in or out excepting through the air inlet and the air outlet. Thus it was possible to analyze the air as it went in and as it came out. Pettenkofer was therefore able to ascertain that during the nine hours' work the laborer had expended in the form of carbonic acid one hundred and ninety-two grammes of oxygen more than he had been able to inhale during that time. To cover this deficit, it was calculated that the workman must have expended twenty per cent. of the provision of oxygen stored in his system. Of course this deficit was to some extent compensated by the night's repose; but, nevertheless, the balance was not re-established. During the night he naturally absorbed more oxygen than he utilized. But as the respiratory organs work more slowly at night the process of recuperation was not sufficiently prolonged. Both Pettenkofer and Voit came to the conclusion that a night's rest was not sufficient to re-establish the normal condition after a day of very fatiguing toil. They were of opinion that the deficit might be equal to ten per cent., and in some cases twenty per cent., of the total stock of energy, and this in spite of the restorative effect of a good night's rest. It was the Sunday rest that alone could enable the body to take up the oxygen lost during the week's toil. The experiment shows clearly enough the fact that manual labor may be too hard and too prolonged. It also shows the need of Sunday rest. But it would be unsafe to compare the steady toil at a wheel in a closed glass case with the very leisurely labor of the majority of workmen who work out of doors.

Suicide During Parturition.—Recently, a case occurred in Wigan, England, where the woman, after some hours of labor, and upon the midwife telling her that it would be necessary to have the aid of a medical man, owing to its being a breech presentation, while the husband went for the doctor, left the house, notwithstanding the protestations of the nurse, and when the doctor and husband returned she was nowhere to be found. The medical man waited some time while a search was made for her, and then left. Next morning her body was found in the canal with the newly-born infant. The shock produced by sudden immersion must have caused the uterus to expel its contents.—*Lancet.*

American Medical Association.

FORTY-THIRD ANNUAL MEETING.

Held in Detroit, Mich., Tuesday, Wednesday, Thursday, and Friday, June 7, 8, 9, and 10, 1892.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

E. E. MONTGOMERY, M.D., CHAIRMAN.

FIRST DAY, TUESDAY, JUNE 7TH.

Some Mooted Points in Obstetrics and Gynecology.—DR. MONTGOMERY gave the above as the title of his address. While expressing a preference for certain procedures, the paper consisted largely in pointing out what had been accomplished in gynecological practice with the forceps, improved Cæsarean section, etc. He thought craniotomy should only be elected when, 1, the child was certainly dead; 2, when still living, but repeated mechanical efforts at delivery and the physical signs indicated that the child was too feeble to long survive birth, the existence of hydrocephalus or other irremediable disease.

The Porro operation could seldom replace the improved Cæsarean section. The author briefly stated why in placenta prævia labor should not be allowed to go on to full term. The mortality to the mother was greatly reduced by inducing labor. In sepsis too much importance could not be placed upon early local antiseptic treatment with a view to prevent a spread of the disease. If the case were a puerperal one, curette, irrigate with solution of corrosive sublimate, followed by simple water, or by solution of peroxide of hydrogen. Then insert gauze. He also approved of treatment of non-puerperal endometritis by dilatation, curettement, irrigation, and drainage, one method being by gauze, the other by the stem. Reference was made to some of the advantages of the Trendelenburg posture in laparotomy, and disapproval expressed of the extra-peritoneal method of treating the stump in super-pubic hysterectomy for fibroids. The author had resorted to sacral resection in one case with satisfaction.

The Relation of the Duration of Gestation to Legitimate Birth.—DR. T. RIDGWAY BARKER, of Philadelphia, pictured the sad moral effect upon the family sometimes following the statement of physicians that the duration of gestation was limited within narrow bounds. By raising unjust suspicions, it had often led to divorce and the blighting of the life of the innocent mother and child. An analysis of a considerable number of cases of pregnancy which were supposed to have run a normal course showed that the duration varied from two hundred and forty to three hundred days or more. Pregnancy dated from conception, and this might not take place for a week or more after the deposition of semen had taken place in the genital tract.

A New Axis-traction—Obstetrical Forceps.—DR. W. B. DEWEER, of Salina, Kansas, presented the instrument and read a paper. The principle of axis-traction was conceded by all observing practitioners as correct. The day was already dawning when authorities would hold that no woman should be delivered by instrumental aid except by axis traction. But the ideas advanced for its production had been more or less conflicting, and some were fallacious. Being convinced that the idea had not yet been fully realized practically he had had Tiemann & Co. make the instrument which he presented, the only important new feature of which was in the construction of the perineal curve, providing for this in their handles, which served for axis-traction. He said it was an aseptic, simple, efficient, and economic instrument. Leaving the blades and shanks with the usual outline to the perineum, he there bent the handles at a somewhat acute angle backward, then again at an obtuse angle to form the hand-grasp in line with the blades. The instrument did away with the complicated, cumbersome, and expensive attachments of the Tarnier and other models. The indicator was thus constantly in the sentient hands of the operator, who at every moment knew through his *conscience musculaire* the direction of traction as well as the resistance.

Report of Cases of Albuminuria of Pregnancy Treated by Chloroform Internally.—DR. J. MILTON DUFF, of Pittsburg, was induced to try chloroform in the albuminuria of pregnancy by a favorable report upon it in the *Southern Medical Journal*, by Dr. A. W. Griggs, in 1890. Dr. Duff related five well-marked cases, in most of which there were convulsions, in some œdema of the legs, coma, in all albumin in the urine. The amount of chloroform given was about fifteen grains, sometimes as often as every hour. The histories of the cases were given in detail, all of which terminated without loss of life to the mother, the albumin disappearing from the urine after labor. Usually relief of the symptoms followed within a few hours, and the quantity of urine if previously diminished, became increased. The author did not attempt to explain this increase, nor, indeed, the action of the chloroform in any sense in these cases. One of the patients was apparently rendered worse by the treatment. In none of the cases was labor induced.

DR. JOSEPH TABER JOHNSON and DR. MCELWAY expressed disapproval of allowing cases of well-marked puerperal albuminuria with active symptoms run along to the great danger of the patient. Labor should be induced as soon as convulsions commenced or threatened.

DR. DUFF replied, in closing, that it was not his intention to advocate chloroform in the albuminuria of pregnancy in opposition to the artificial termination of labor. As there were circumstances in which one might not induce labor, he had tried the internal use of chloroform with a view to determining its real value.

Judging from his slight experience it would prove useful in some, negative or harmful in others. Perhaps this was due to a difference in cause of albuminuria of pregnancy in individual cases. Being asked whether he had tried chloroform in the albuminuria of Bright's, he said that through the kindness of friends it had been tried in nine cases, with the result, in all, of making the patients worse.

Interference in Delayed Labor.—DR. GEORGE C. MOSHER, of Kansas City, opened his paper on this subject with a reference to some of the peculiar methods resorted to by uncivilized races in delayed labor, and passed to a review of those recommended by lights in the profession to-day. A warm drink, or tea, generally recommended by the laity, was harmless, might do some good through its slightly stimulating effects, and should not be discountenanced, as it led the friends and patient to feel that something was being done. Objections were offered to the use of ergot at this stage. Chloroform by the rectum might prove useful. There were also circumstances under which a hypodermic injection of morphine with atropia was indicated, especially in primipara in whom the contractions, which at first were powerful, had become feeble, give nature a chance before resorting to forceps. The greater his experience became, the less frequently did he find it necessary to use instruments. Of course no case should be allowed to go to exhaustion before resorting to energetic means. In advocating conservatism in the use of forceps, he did not mean timidity. His object in writing the paper was not to advance any new theory or method, nor any hobby, but rather in referring to well-known methods to elicit a discussion on the best.

This paper and the next were discussed together.

The Treatment of Posterior Rotation of the Occiput During Labor.—DR. EDWARD P. DAVIS, of Philadelphia, read the paper. Under posterior rotation he included what American writers meant by the posterior position.

It was simpler and more intelligible to speak of only two positions, first and second, as did European writers. In the vast majority of the cases during labor the occiput turned toward the symphisis, but occasionally it turned posteriorly, giving rise to what had been termed the posterior position. In some cases an unusual mechanical condition in the pelvis or child's head caused the unfavorable posterior rotation, but often no cause could be found.

Normal rotation of the head required, 1, a normal proportion between the size of the head and pelvis; 2, a flexed position of the head; 3, normal forces, *i.e.*, normal contractions of the uterus and resistance offered by the pelvic floor. If anyone of these were absent, perversion of rotation was likely to occur. The author urged the necessity for early measurement of the pelvic canal in all cases of pregnancy, and if normal labor at term was found to be impossible, resort to induced labor. The author disagreed with those who saw little or no value in the pelvimeter, and presented an instrument made by Tiemann & Co.

If possible, when the occiput was posterior the head should be turned without a resort to forceps. This could sometimes be done by giving a little chloroform, and introducing the whole hand, palm placed over the vertex, position corrected and retained until a contraction took place. One should also take advantage of posture. For instance, the posture often assumed by women, kneeling forward upon the bed, favored anterior rotation. Where the expulsive efforts were at fault, tea, coffee, alcohol, anæsthetics, etc., might restore unity and tone. The author showed forceps, and emphasized the necessity for their proper application when their use was a necessity. Where normal delivery was impossible, conservative Cæsarean section might be indicated before the head had become impacted and made craniotomy necessary.

Those who discussed the papers agreed in general with the authors, except Dr. C. R. Reed, of Iowa, who admitted using the forceps a great deal in delayed labor, and said that he had had no occasion to regret it. His practice, however, met with decided disapproval from the others.

Dr. Davis said an enema or laxative often hastened a delayed labor. He urged that there were only two indications for the use of forceps, *i.e.*, danger to mother or danger to child.

Second Day, Wednesday, June 8th.

Delivery through the Abdominal Walls versus Craniotomy.—Dr. George J. McKelway, of Philadelphia, quoted the opinions of A. P. Dudley, E. H. Grandin, and of others, mostly in favor of selective Cæsarean section *versus* craniotomy. This was the firm ground taken by the author. It had become a question less of taking one life to save another, than of adding slightly to the risks for the mother in order that both lives might be spared.

The author thought craniotomy or embryotomy justifiable only where the child was dead, or was a hydrocephalic monster. The need of an early examination in pregnancy was emphasized.

The ground taken by the author was that upon which Drs. Newman, E. P. Davis, Reed, Wathens, Barker, Zincke, and L. Smith, stood, while Dr. Ashton held that the mother should decide whether craniotomy or laparotomy should be performed. Dr. Rohé, of Catonsville, Md., thought the question not so simple as to permit of being answered by the general statement that we were not justified in taking life. For instance, a woman having been subjected to ineffectual efforts at delivery for two days, was not in condition to undergo a capital operation like Cæsarean section, and one would have to decide according to the case whether he should or should not destroy the child by craniotomy. Each case should be decided on its own merits.

Impairment of the Voice in Female Singers Due to Disease of the Sexual Organs.—Dr. C. H. Leonard, of Detroit, had found scarcely any mention, aside from a paper by Von Klein, of Dayton, of changes in the voice of singers due to disease of the uterus or ovaries. Dr. Von Klein had laid principal stress upon disease of the ovaries in causing such change of voice, whereas Dr. Leonard thought disease of the uterus was the principal cause either in itself or as productive of ovarian change. Several cases had come under his observation in which singers had regained their voice by relief of uterine trouble, and in two laryngeal spasm occurred at every uterine application. He attributed the laryngeal trouble to reflex action, tracing the connection through the sympathetic system supplying the uterus, to the pneumogastric, and finally to the spinal accessory supplying the larynx.

Hysterical Mania as a Complication of Gynecological Cases.—Dr. Ely Van de Warker, of Syracuse, read the paper. Without attempting to say what was hysteria, he expressed the belief that its phenomena were manifest in the intellectual field. The bodily conditions leading to it were largely subjective. The term hysterical mania, therefore, was not used in the sense of a diseased mind originating in a delusion, but rather that the mind had lost the power of diverting itself from certain fixed ideas about which it circled in an endless iteration. Mental function might be perverted without apparent organic disease. While asserting that hysterical mania manifests itself along certain distinct lines which enabled the gynecologist to distinguish such cases from true mania, yet the author observed that asylum superintendents, for want of training in general or certain lines of special medicine, grouped the several classes of cases together to the great detriment of the hysterical patient. He believed that ten per cent. of females under thirty-five who were inmates of asylums could be restored to society by proper treatment and removal from the influence of the insane. Removal from the asylum was essential to recovery on account of the imitative tendency of hysterics. These points led the author to condemn the existing laws, in New York particularly, which often led to the appointment of asylum superintendents who had no knowledge of gynecology and other specialties, and made no provision for giving inmates the benefit of the advice of those trained in medicine aside from asylum experience.

The author related some cases of hysterical mania cured or greatly improved by gynecology. Referring again to neglect of attention to disease of the genital organs of women on the part of asylum superintendents, the author said reform must start from indignant protests on the part of general practitioners rather than from managers of the institutions.

Influence of Parturient Lesions of the Uterus and Vagina in the Causation of Puerperal Insanity.—Dr. George H. Rohé, of Catonsville, Md., read a paper on this subject. Four cases were reported, in each of whom there was rupture of the perineum, laceration of the cervix, and morbid conditions of the ovaries and tubes. In all, laparotomy was performed and the uterine appendages removed. Two of the cases, one of ten weeks' and the other of eighteen months' duration, recovered their normal mental condition after the operation. The other two cases, both of five years' duration, and in a condition of partial dementia, were very much improved.

The cases are held to justify the following conclusions:

1. Puerperal insanity is, in at least the majority of cases, an infection psychosis.

2. Without rejecting the influence of other factors, such as heredity, anæmia, exhaustion, mental shock and distress, careful observation will show that few cases of puerperal insanity occur without preceding or coincident puerperal infection.

The reasons for this opinion may be briefly summed up as follows:

1. Puerperal insanity occurs in the great majority of

cases within the first ten days after delivery—about one-half in the first five days—the same period during which puerperal infection usually occurs.

2. It is usually accompanied by elevation of temperature and other evidences of febrile disturbance.

3. The clinical form in which puerperal insanity manifests itself is, in the majority of cases, that of acute delirious or confusional mania. Depressive states are rare except as secondary forms. In other words the most frequent condition is one most closely resembling febrile delirium.

4. The death-rate is much higher than in simple mania. Death occurs from exhaustion, usually with high temperature and rapid pulse.

5. Post-mortem examinations, though apparently infrequent in these cases, have shown grave involvement of the pelvic viscera.

6. Examinations of the pelvic organs during life show lacerations of the perineum and cervix uteri (facile channels of infection in the puerperal woman). As secondary conditions, are found intra-pelvic (peritoneal) inflammations, and consequent abnormal locations, fixations, and congestions of the uterus, tubes, and ovaries.

7. The results of operations seem to show that removal of local sources of irritation increases the chances of recovery from the mental disease.

The two papers were discussed together. Dr. Rohé said that to an extent Dr. Van de Warker's restrictions upon asylum managers were just, yet in Michigan, as well as in Maryland, if not in other State asylums, attention of recent years was being given lesions of the genital tracts, etc., in insane patients, with more or less happy results, as indicated in his paper.

Officers Elected.—*Chairman*, Dr. John Milton Duff, of Philadelphia; *Secretary*, Dr. M. B. Ward, of Topeka; *Executive Committee*, Drs. Montgomery, J. T. Johnson, and Eastman.

The Prevention of Stitch or Mural Abscess and Ventral Hernia Resulting from Abdominal Surgery.—Dr. W. H. Wathen, of Louisville, read an abstract of his paper on this subject. He believed these troublesome and sometimes dangerous complications might be usually prevented. Incision should be by knife, if possible through the linea alba to prevent injury to the muscles; scissors should not be used unless in dividing the peritoneum, nor hæmostatic forceps if it could be avoided; he now seldom used either. Retractors were seldom needed, and were liable to do injury by bruising the tissues. The peritoneum should not be separated from the walls. Injured tissues should be cut away. Select a stitch which would most likely avoid abscess and hernia. He preferred the following method, which he did not claim to be at all novel: With a straight or curved needle, begin at the lower end of the wound and close the peritoneum with continuous stitch; the deep fascia was next closed, in the same way, then the superficial fascia and fat. The suture was then cut and the end buried. The skin was united by superficial sutures of silk-worm gut. He preferred kangaroo tendon to catgut because they were more easily made and would not be absorbed until union was perfect. The dressing should be held by adhesive plaster, and should be strictly aseptic.

The Operative Treatment of Ventral Hernia Resulting from Abdominal Surgery.—Dr. Tod D. Gilliam, of Columbus, read this paper. The technique which he had adopted would, he said, be recognized as an old-time friend in a new garb, and consisted in denudation of an elliptical surface, turning in the redundant tissue, and uniting by suture; being similar to the operation for cystocele. The preliminary treatment was important—strengthening the patient, avoiding flatus, baths, washing of the abdomen a number of times and for days previous to operation, Trendelenburg posture once or twice daily, etc.

Persistent Sinuses Resulting from Abdominal Section.—Dr. Andrew F. Currier, of New York, treated of this subject. First he dwelt upon the natural reparative powers manifest in sinuses and injuries. Where a sinus formed or persisted the causes were, 1, constitutional; 2, irritant; 3, septic. The term predisposing might be more appropriate than constitutional. Among irritative agents were drainage-tubes, sutures, etc. The treatment was expediency, palliative measures, and radical measures. Nature not infrequently cured the sinus if one kept up the patient's nutrition. Recent more radical procedures might even fail. Violence in applications or operations should be avoided.

A prolonged discussion followed on the three papers.

Dr. E. W. Jenks did not believe abscesses were always due to sepsis, for with the most scrupulous care he still sometimes had abscesses; they seemed to come from within rather than from without, from the constitutional condition. Idioform had no value except for its perfume. He preferred glass to gauze as a drain.

Dr. McMurtry, of Louisville, had had but one case of ventral hernia following operation. Yet early in his experience he frequently had mural abscess, seldom later, because experience had enabled him better to carry out asepsis. Abscesses, he believed, were due more frequently to defective aseptic work than to strangulation. A potent factor in causing ventral hernia was in allowing the patient to get up early, say by the tenth day. The drainage-tube played only an unimportant part.

Dr. S. C. Gordon, of Maine, opposed the use of the drainage tube as unnecessary, for the operation should be aseptic. Where sepsis was present in the cavity he used bichloride solution.

Dr. J. H. McIntyre, of St. Louis, spoke strongly for the drainage-tube. How were we to know that the cavity had been rendered aseptic. He would expect as much harm from bichloride in the abdomen as from possible septic matter. He used the drainage tube constantly, yet had had but two cases of mural abscess in six years.

Dr. R. B. Hall also advocated the advantages and harmlessness of the drainage-tube in abdominal operations.

Dr. G. M. Edebohls, of New York, thought that without the introduction of sepsis, mural abscess would not occur. Chromatized catgut was more durable and better than kangaroo suture in closing the abdominal wound. He used silk-worm for deep sutures, catgut for the superficial. In operating for hernia, it was not sufficient simply to bring the edges of the muscles together; they should be made to overlap, and the fascia be united separately.

Dr. E. Ricketts looked upon the drainage-tube in abdominal surgery as the governor to the steam engine. Yet he would not drain in every case. Mural abscesses arose oftener from within than from without, or the introduction of sepsis.

Dr. Willis P. King, of Kansas City, drained whenever he flushed the abdomen, for the same reason—fear of leaving something foreign. Formerly he had had herniæ, but none since he began to unite the parts separately.

Dr. W. E. B. Davis, of Alabama, objected to the use of antiseptic fluid in the peritoneal cavity, as where some septic material was present it was more likely, because of irritating properties, to cause peritonitis, whereas without such irritant the peritoneum could better dispose of the septic material. The drainage-tube had perhaps been used where it could have been dispensed with, but it was comparatively harmless, and those who used it frequently got better results from it in cases really demanding it than others, because of greater experience.

Dr. Gilliam said Dr. Edebohls had obtained an erroneous idea of his operation for hernia in supposing that it included lapping only of the skin. He included muscle and fascia.

Pathology of Intestinal Obstruction Following Abdominal and Pelvic Operations.—Dr. W. E. Ashton, of Philadelphia, read the paper. The causes of such obstructions were, 1, adhesions between the intestine and

raw surfaces; 2, paralysis of the intestine; 3, local spasms of the intestine; 4, impacted fæces; 5, dense inflammatory lymph; 6, adhesions between coils of intestine, or between the gut and neighboring parts, due to traumatic inflammation; 7, kinking of the intestine due to faulty surgery; 8, including loop of intestine in suture; 9, slipping of coil of intestine into abdominal wound, etc.

Cases were cited, a few in the author's experience, illustrating these different forms. By far the greater number of cases of obstruction fell under the first class, being due to adhesions between the intestines and raw surfaces. He thought that if the raw surface was near the normal situation of the coil, obstruction was less likely to take place should adhesions form. To prevent a peristalsis, the present practice of preceding the operation by salines was a good one; tympanites should be avoided.

The Influence of Delayed and Incomplete Operations upon Mortality in Pelvic Surgery.—Dr. L. S. McMurtry, of Louisville, read a paper with this title. Among conditions in which delayed or incomplete operations had proven disastrous, pus-tubes and fibroid and other tumors stood out conspicuously. It had been shown by Dr. J. T. Johnson that fibroids of the uterus often went on to cystic and malignant degeneration after the menopause.

Tubal pregnancy had frequently resulted fatally by delay. Who would wait and temporize if the femoral artery were divided? In ruptured ectopic pregnancy, one should cut down at once and arrest hemorrhage. Regarding incomplete operations, while the exploratory incision was of great importance, yet where a pathological condition was found one should not only attempt its removal, but complete the procedure. His object in writing the paper had been, he concluded, to impress promptness and thoroughness in applying advanced principles of surgery.

Third Day, Thursday, June 9th.

The discussion of the papers read by Drs. Ashton and McMurtry was taken up.

Dr. E. B. Massey, of Philadelphia, took exception to the general statement that disaster was usually to be attributed to delayed or incomplete operation. He believed, on the contrary, that greater conservatism was called for with regard to proceeding to major abdominal surgery. He had known many patients submitted to a major operation cured only after they had gone to a general practitioner for other treatment. He predicted that the time would come when serious interference with abdominal and pelvic cavities would be limited to cases in which pus had been demonstrated to exist. He had recently been making use of the electric light in diagnosis here. Healthy tissues transmitted the light better than diseased, better than pus or necrotic tissue. Strong electric light in the vagina, in a dark room, would illuminate the tissue as far up as the umbilicus. Thus he had recently been able to differentiate between tubal pregnancy and pus in the tube.

Dr. Hall cited a case to show that there was usually too great delay among general practitioners in calling in the operating gynecologist.

Dr. Joseph Taber Johnson further emphasized the evil consequences of delayed operations, particularly in uterine fibroids. The opinion had prevailed that these would cease to give trouble with the appearance of the menopause, but it had been shown by himself and others that instead of receding the tumors took on malignant degeneration and made an operation much more dangerous in itself and less likely to prove successful. These papers would prove very useful in calling attention to the causes of our failures.

Drs. F. H. Martin and Ricketts called attention to some measures for preventing the pathology of obstruction. Dr. Ricketts found strychnine to overcome intestinal paresis.

Dr. W. E. B. Davis, of Alabama, dwelt upon misplacement of the intestines as a cause of obstruction. Obstruction oftener followed operations in which the intestines were taken out of the cavity than in other cases.

Tolerance of the Peritoneum.—Dr. E. P. Davis thought it important, in the line of preventing adhesions, to know what substances were least irritating to the peritoneum. The French had found that iodoform was least irritating, next was boric acid; the peritoneum over the liver was less irritating than elsewhere.

Dr. Ashton gave one-fifteenth of a grain of strychnia four times a day for about three days before and after abdominal section in order to obviate intestinal paresis and tympanites.

Micro-organisms in the Diseased Endometrium and Surgical Interference.—Dr. Ernest Laplace, of Philadelphia, based this paper upon some studies which he had made in Koch's laboratory in 1887. From those studies he concluded, 1, that the normal mucous membrane of the uterus and cervix is a harbor for vast numbers of micro-organisms, most of which are known to us, some unknown, yet are poisonous to guinea-pigs; 2, the inflamed membrane contains the same kind of micro-organisms, but the vast quantities of superficial exfoliating cells also contain them; 3, in chronic endometritis, besides the secretions containing infectious micro-organisms, the mucous membrane and fibrous tissue became greatly hypertrophied under the continuous development of these organisms. In this chronic condition, whether simple or gonorrhœal, the germs were also in the epithelium and fibrous tissue. The uterus with normal secretions did not favor the development of the pathogenic micro-organisms. A most frequent cause, giving rise to a condition favorable for their development, was cold with congestion and pouring out of serum. The treatment which suggested itself was removal of the cause, curettement and cleansing of the uterus, sterilizing of the mucous membrane, and, he might add, drainage by gauze. For sterilization he recommended acid sublimate solution.

The discussion was participated in by Drs. Massey, McKelway, C. R. Reed, Albert Vanderveer, R. T. Morris, Nelson, S. C. Gordon, Ashton, W. E. B. Davis, L. Smith, E. P. Davis, and others, most of whom dwelt upon the treatment of endometritis.

Dr. Massey thought it had not been proved that germs existed within the uterus under the normal condition; spoke of electrical treatment with decomposition of a chemical for antiseptic purposes.

Dr. Vanderveer emphasized the value of treatment by dilatation, thorough curettement during inflow and outflow of boric-acid solution, and packing with gauze.

Dr. R. T. Morris felt great security with peroxide of hydrogen and gauze.

Hysterectomy Without Pedicle.—Dr. S. C. Gordon, of Portland, Me., read this paper. He believed the only appropriate treatment for fibroids of the uterus was total extirpation. Electricity and removal of the appendages might get relief, yet the tumor remained.

Hysterectomy in these cases would come to be as safe as ordinary ovariotomy. It had so proven in his hands. He advocated total extirpation. He ligated the broad ligaments on each side, proceeding down to about the uterine artery, with over and over suture, closing the folds of the ligament as it was cut free from the uterus. As the uterine artery was approached he dipped the suture below this and secured the artery within the loop before division. At this time he divided the peritoneum from the uterus in front and behind, separating it from the bladder and utero-sacral attachments. These attachments of the peritoneum in front and behind were easily held up by forceps until the attachment of the broad ligament on each side was completely separated and secured by suture, this being continued across the vaginal opening by uniting the flaps of the peritoneum. This closed the roof of the vagina, and the uterus could be lifted out. The most troublesome part of the operation consisted in securing the uterine artery and dissecting the uterine

attachments to the bladder and vagina, especially when the cervix was very long, because of the time required.

In one case he had secondary hemorrhage at the end of two weeks, which proved fatal.

"The Technique of Hysterectomy for Fibroids" was discussed by Drs. Eastman, Van de Warker, Martin, McIntyre, Nelson, J. T. Johnson, Hall, and Baer.

Dr. Johnson thought one should not limit himsef to any one method for all cases, but should familiarize himself with all and apply them as best could be done in the individual case.

Dr. Baer and some others thought it best to retain the normal contour of the vagina by leaving the cervix.

Dr. Van de Warker objected to operating in all cases, for some women carrying fibroids were in no wise sufferers. He thought Gordon's operation was essentially Freund's.

Dr. Nelson referred to what he had before said in favor of ergot in some cases. He thought electricity acted in the same way, by influencing the circulation.

Dr. Gordon said his operation was a suture operation, while Freund had used ligature—an important difference. All women with fibroids suffered, and should be operated upon. He had operated by this method in about twelve cases, with two deaths, including the one with secondary hemorrhage.

Combined Gynecological Operations.—Dr. George M. Edebohls, of New York, read this paper. The tendency of modern gynecology is to progress in a surgical direction. The uncertainties and unreliability of other methods of treatment, as compared with the results obtained by surgical measures, are proverbial. With the rapid strides forward of surgical gynecology, this contrast is daily becoming more accentuated. Increased confidence in results growing from increased experience and progressive skill will incline the individual operator more and more to trust to surgical resources. Many cases require more than one gynecological operation to effect a cure. All gynecological operations required in a given case should, at the present day, as a rule almost without exception, be performed at the same sitting. The patient has a right to expect this from the expert claiming to possess the highest degree of operative skill. That this will be the standard of the near future, the author does not doubt. Success in combined gynecological operations presupposes, first of all, perfect asepsis and a not too prolonged anæsthesia. The duration of the latter need but very rarely exceed one and a half hour, even in the most difficult cases. Other things necessary are the requisite degree of operative skill and dexterity, sufficient and efficient assistance, a perfected technique of the various operations attempted, and an instrumentarium suitable to rapid work. The author described his instrumentarium and the technique of the various gynecological operations as practised by him.

Combined gynecological operations may be divided into two general classes: 1, Combinations into which a laparotomy does not enter; 2, combinations of which a laparotomy forms part.

The expert operator should be able to perform any required combination of operations of the first class within the time limits of safe anæsthesia. The same statement holds good of the combinations of operations of the second class into which a simple laparotomy enters. When a difficult laparotomy forms part of the combination, the patient's interests may occasionally be better served by operating at two sittings. Examples of combinations of both classes were given from the author's practice. To cite but one example, the author had a number of times, in cases of complete procidentia uteri, performed curettement, amputation of the cervix, anterior colporrhaphy, colpo-perineorrhaphy and ventrofixation of the uterus at one sitting, doing the five operations within seventy-five minutes. As a result of his experience and success with plastic work, he considered total extirpation of the uterus for prolapsus justifiable only under very exceptional conditions. There is no excuse for a mortality in combined operations of the first class. The mortality of combinations into which a laparotomy enters will depend upon that of the special intra-abdominal operative interference required.

The author concluded his paper with a frank recital of all his failures in combined gynecological operations.

Five Cases of Ovarian and One of Uterine Tumor with Twisted Pedicle.—Dr. Joseph Taber Johnson, of Washington, read the history of the cases. The histories were similar in many respects. In only one had he diagnosticated twisting. In two pregnancy was supposed to be the cause of enlargement. In all, symptoms of pain, elevation of temperature, and increased pulse came on suddenly. In all the patients were apparently *in extremis*. In all he found a tumor with twisted pedicle, in five an ovarian tumor, in one a fibroid, growing from the side of the uterus to which it was attached by a band about two inches wide. The peritoneum was dark, the tumor black, its circulation almost completely shut off by the twisting of the pedicle.

Notwithstanding the fatal issue staring him in the face, all the patients recovered. Out of two hundred laparotomies performed by himself, and two hundred or more seen at the hands of others, these six were all in which twisted pedicle with strangulation was present. One valuable lesson learned was that, had these tumors been recognized early and removed, the patients would not have been exposed to the risks of sepsis attending twisting of the pedicle.

Fourth Day, Friday, June 10th.

Vaginal Hysterectomy for Cancer of the Uterus Complicated by Pregnancy.—Dr. Albert Vanderveer, of Albany, showed in this paper the very great mortality in cases of carcinoma of the uterus, complicated by pregnancy, without operative interference. No other disease presented a darker picture. He had done vaginal hysterectomy in one case, at the second month, the mother recovering. There had been fifteen other cases reported, all successful. Briefly the treatment of carcinoma of the uterus might be summarized as follows: In all operable cases where the pregnancy was not advanced beyond the fourth month, do a vaginal hysterectomy at once. In all operable cases between the fourth month and term, as a rule, complete extirpation of the uterus by Freund's method, as modified by Zweibel, and in inoperable cases delivery at term, or a supra-vaginal hysterectomy of the pregnant uterus.

Porro's Operation.—Dr. E. P. Davis remarked upon the important fact in connection with this paper that, by improved incubation, etc., the date of viability of the child had come to the twenty-eighth week or earlier. Where the pregnancy had gone to the point of viability, he recommended Cæsarean section, putting iodoform into the vagina before making the incision, thus preventing a measure infection of the wound from the vagina.

A Report of Experiments Germane to the Subject of Abdominal Supporters After Laparotomy.—Dr. Robert T. Morris, of New York, gave the results of experiments upon rabbits, going to show that in laparotomy operations the structures should be united separately. It took only seven days for the united peritoneum to become as strong as normal; about fourteen days were required for complete repair of the muscular and fibrous walls. The skin became of full strength at the end of eighteen days. He argued that it was absurd to apply abdominal supports after laparotomy for the purpose of preventing hernia if the surgeon had done his suturing aright. If the suturing were wrongly done the supporters would still be useless. The author used only catgut for sutures and ligatures. He had not had as yet any hernias after laparotomy, and would feel that it was his own fault should he have any. He explained the necessity for four tiers of sutures after appendicitis operations.

Dr. A. F. Currier had adopted the measure laid stress upon by Dr. Wylie, of introducing a separate line of sutures in the fascia. The last two years he had made the incision, not through the linea alba, but through muscle. He had long thought the ordinary abdominal supporter was of little value after laparotomy. He did, however, apply a broad strip of rubber adhesive plaster, and believed it gave greater security against hernia.

Dr. McKelway, of Philadelphia, thought Dr. Morris was right in the assertion that where union took place a supporter would not be necessary, but he had admitted weakness in cases in which an abscess had formed, and how were we to know that some source of weakness was not present in operations on patients. He emphasized the exceeding importance of uniting fascia to fascia.

Colpo-Perineorrhaphy.—Dr. Edward W. Jenks, of Detroit, in this paper gave some general considerations of tears of the perineum and their repair, and then described the method of operating which he had practised for fifteen years or more with slight variations. The first description which he had given of his method, which he admitted may not have been exclusively original with himself, was published in the *American Journal of Obstetrics* fifteen years ago. Since then he had performed the operation much oftener than one hundred times, and naturally during so large an experience had made some improvements.

Four important things were to be attained in secondary operations upon the perineum: 1, to repair the loss of power and function of the lower portion of the rectum and vagina; 2, to restore the normal sustaining quality of the posterior vaginal wall for the anterior vaginal wall and bladder; 3, to provide as much support for the uterus as the perineum naturally gave; 4, to cure the many distressing symptoms of which these patients complained. Any surgical procedure which did not accomplish these results was not successful.

He called his operation colpo-perineorrhaphy, because it was more than an operation upon the perineum alone. To secure the best results it was necessary that the skin flap extend as high within the recto-vaginal septum as there were signs of slack or redundancy of the posterior wall. While this was the most essential feature, yet he laid some stress on the method of introducing the sutures, although he admitted that the denuded surfaces could be coaptated by sutures introduced more or less variously, and coaptation was the essential point. He employed scissors for denudation and silk-worm gut for suture, but admitted that silver wire, except for certain objections, was the ideal suture. In his operation, unlike in most others, the first two sutures were the longest and most important. The first entered half an inch from the commencement of denudation and came out where the denudation ceased above, being passed in deeply. It was crossed by the second. He denied that the operation involved any serious operation.

In the discussion Drs. W. W. Potter, Dow, and Newman, expressed their approval of Dr. Jenks's operation, but Dr. Dow inserted his suture differently.

Ovariotomy During Pregnancy.—Dr. W. H. Myers, of Fort Wayne, reviewed this subject critically, and related a case in which he removed a multilocular tumor weighing about ten pounds, complicated by pregnancy. Soon afterward the woman aborted. He used a drainage-tube. There was some fever, but after the twentieth day she went on to good recovery. He thought the diversity of opinion prevailing regarding the management of these cases was due to a division of the profession into obstetricians and operating gynecologists. Among the methods which had been recommended were non-interference, puncture of the cyst, induction of premature labor, Porro's operation, and ovariotomy. Objections to all but the last method were given, especially to the first two.

Dr. W. W. Potter was surprised that there should yet be any doubt as to the propriety of ovariotomy, when the diagnosis of tumor complicating pregnancy was clear. He had done a double ovariotomy at the fourth month; the pregnancy continued and a healthy child was born at term.

Dr. Murphy had removed an ovarian tumor weighing about thirty-seven pounds, pregnancy at about the third month, continuing until a healthy child was born at term.

Dr. E. P. Davis thought Dr. Myers would not have been troubled with fever in his case had he not employed drainage.

Dr. R. J. Morris, of New York, had removed an ovarian tumor weighing fifty pounds at the fifth month of pregnancy, and the patient went on to be delivered normally at term. In another case the patient made a good recovery, but aborted. Here he had made ventral fixation.

Dr. Dow presented an instrument for facilitating operations on the cervix uteri.

A vote of thanks was given the chairman, Dr. Montgomery.

The Section adjourned.

AMERICAN SURGICAL ASSOCIATION

Annual Meeting, held in Boston, May 31, June 1 and 2. 1892.

First Day, Tuesday, May 31st—Morning Session.

(Continued from p. 672.)

It is in the surgery of the head and spine that the greatest advances have been made, the largest number of new procedures introduced, the most brilliant operations done; and in these regions more than anywhere else the surgery of to-day is a new surgery, much of it the growth of even fewer years than those included in the lifetime of the Association. More and more constantly are all depressed fractures of the skull being treated actively, and basal fractures antiseptically. Stronger and stronger is becoming the conviction of surgeons that fractures of the spine, associated with evidence of pressure upon or injury of the cord, should not be left to nature, if the general and local symptoms indicate lesions that can be removed or relieved by elevation or extraction of vertebral fragments, or the lessening of intra-dural tension through opening of the sheath.

It has been proven to be wise to treat bullet-wounds of the brain like other punctured wounds of the organ, by exploring, cleaning, and draining the track; and occasionally it has been found possible to extract the ball through the wound of entrance or a counter-opening in the skull. The future must determine how far it is wise to go in the way of effecting removal of the bullet, and this must largely depend upon previously ascertained extent of liability to the supervention of epilepsy and mental disturbances, weeks, months, or years after the lodgement of a ball that at the time of injury did but comparatively little damage, or damage at least that was spontaneously recovered from.

Trephining for epilepsy following injury of the skull is no new operation, but of late such treatment has been quite largely employed, not only in cases where there has been an old fracture or contusion, but in those in which, by application of the now well-established rules of cerebral localization, it has been possible to determine the place of a meningeal thickening, or of a limited chronic encephalitis, or a new-growth, solid or cystic, acting as an exciting cause of motor disturbance. Electrical stimulation of the exposed cortex has been made to indicate with exactness a diseased area, the removal of which has been followed by relief, temporary or permanent, of the spasm symptoms. The attained perfection of operative procedures has reduced the mortality-rate to a very low figure, and even the after-presence of a gap in the skull has been prevented by reimplantation of the removed bone. Unfortunately, in very many cases of

recovery from operation, in a few weeks or months, or it may be years, the convulsive seizures will come on again. An established "epileptic habit" is independent of the original lesion, and after a certain time, which is a very uncertain one, the patient can no longer be assured that, the cause removed, the effect will cease. But, for all this, the morbid condition is so disabling, the relief afforded may be so great, the risk run is comparatively so small, that after proper and properly continued yet unavailing medicinal treatment, an epileptic in whom the seat of the disease can be fairly well located should become the subject of operative interference.

Trephining has also been done because of the existence of long-standing severe headache, and in cases in which the thorough application of the therapeutic test has proved that the cephalalgia does not depend upon a cause that can be reached and removed by drugs, the operation may certainly with propriety be recommended.

Considerable sections of the skull have been taken away to permit of the expansion of the microcephalic brain, but though improvement in mental condition in certain cases has followed such linear craniotomy, at the present time the operation seems to be of very questionable utility. Before it is to be accepted as an advisable method of treating feeble-minded children, further investigation must be made into the causes of arrested cerebral development, and how far it is productive of, and how far consequent upon, premature ossification of the cranium.

Insanity of traumatic origin has, in a very large proportion of the few cases surgically treated, been much improved or cured. because, we may believe, of relief of "intracranial fluid pressure," and even general paretics have been thought to have been benefited by trephining.

A few years ago, who would have dreamed of opening up the lateral sinus and removing from it a pyogenic thrombus? Yet it has now been done several times, and with success.

In not a few cases intracranial abscesses have been definitely located and operatively relieved.

But the most brilliant chapter in this history of brain surgery in recent times is that relating to tumors. There is set forth in it not only what has been done, remarkable as it is, but also the unity of medicine and the interdependence of its various departments. It is because of the work of the anatomist, the physiologist, the pathologist, the neurologist, that it has been rendered possible to locate, with close approximation to exactness, the position of the neoplasm and its character; without knowledge of which the skill of the surgeon and the most careful operative technique would be of little or no avail. Even the experimental therapeutist has played a part, because of his demonstrations of the influence of morphia upon the intracranial circulation. Though in but a small percentage of cases of tumor has it been, or perhaps can it be, practicable to effect removal because of location or pathological character, yet when it is so the gain is enormous. even though the relief afforded be but temporary, as in dealing with certain growths it must be.

Much less operative work has been done upon the spine than upon the head. It has had for its object the evacuation of abscesses, the relief of paralysis, and the removal of tumors pressing upon the cord, and has been in a high degree satisfactory and full of promise.

As never before, the congenital malformations—meningocele, encephalocele, and spina bifida—have been subjected to surgical treatment, and that with an increasing success, as improvements have been made in the methods of execution. Renewed attempts have been made to permanently get rid of intra-ventricular effusions by tapping and drainage, but the results have not been what might be desired, and that whether the old route to the ventricle has been followed or the new lateral one.

In the special departments, as in general surgery, these last ten years have been busy ones, and each may justly claim that there has been advance made in the recognition of disease and improvement in its treatment. But consideration of the work done in them does not concern us here.

Any retrospect, be it never so hurried, of the work of the decade furnishes good warrant for pride in what has been, and high hopes of what is to be. The world over, educated minds and trained hands are busy with the problems of cause, of course, of termination, and seeking out surer, safer, and speedier means of relief, therapeutic and operative. Week by week, and month by month, what is accomplished becomes free and common property; everything is proven and the good held fast. What will be the outcome of all this thinking, and experimenting, and operating, and writing, even in the near future, who would dare to predict? American surgeons have had not a little to do with the work in the past. Fellows of our own Association, some of whom have fallen asleep, have been closely identified with the discovery, the early adoption, and the thorough testing of not a few methods of treatment, and we may expect with confidence that it will be with us hereafter as it has been, and yet more.

As an organized body, certain duties rest upon the Association. Representing the surgery of a country of wide extent and of very varied climate and soil, of a people of many racial origins, there should be conducted by it a series of collective investigations, which, for example, might show the prevalence, and as far as possible the more remote determining causes, of certain surgical diseases, chief among which is cancer; or the influence of the local conditions, as of altitude, of average temperature, and of moisture upon the healing of wounds; or of the relative resisting power to the action of morbific organisms of the descendants of immigrants from different nations, still more members of the several color-races, four of which are to be met with within our boundary lines in numbers large enough to be of value in an investigation of this sort. From our meetings, year by year, should go out to the world reports, as it were, of the surgical state of the nation, and, as far as can be ascertained, the reasons therefore as found in place, in race, in occupation, and in social position.

In the personnel of the Association, the years that have gone by have brought much change. It could not but be so. Thirty-three of the Fellows have passed away, leaving to us a memory of worth, of learning, and of skill. Since our last meeting Agnew, and Campbell, and Johnston, and Kinloch, and Peck have rested from their labors. Each, honorable and honored in his own place and in his own way, aided humanity and advanced medicine, and each will long be held by us in kind remembrance.

The Treatment of Uncomplicated Fractures of the Lower End of the Humerus, was the title of a paper by Dr. John B. Roberts, of Philadelphia. Pa.

The following are the conclusions presented:

1. In the treatment of fractures of the lower end of the humerus the divergent angle between the axes of the arm and forearm must be preserved; and hence, dressings which interfere with the normal difference in level of the radius and ulna are not permissible.

2. Fractures of the lower end of the humerus of ordinary severity are, as a rule, more successfully treated in the extended than in the flexed position.

3. Because the "carrying function" is less liable to be impaired.

4. Passive motion at an early date is harmful; and should be deferred until union has occurred and the dressings have been finally removed.

5. Good results as to anatomical conformation and as to motion are generally to be expected, and can usually be obtained.

6. Recent fractures in which satisfactory coaptation is not obtainable under anæsthesia. may with propriety be subjected to exploratory aseptic incisions. Old fractures, in which deformity and impairment of function are marked, may, within certain limitations, be subjected to

refracture or osteotomy, for the relief of these conditions.

Dr. John E. Owens, of Chicago, said that he had never treated fractures of the lower end of the humerus in the extended position. The treatment of such fractures in the extended position seems to recommend itself for the following reasons: In the extended position there is no room in the olecranon fossa for neoplastic deposits; the great superabundance of soft tissues in front of the joint when the arm is flexed marks the symptoms; the soft tissue in front of the arm presents more opportunity for laceration and cicatricial contraction; no traction is made upon the vessels and nerves; the natural angularity between the arm and forearm is preserved.

The speaker had experienced considerable timidity in the treatment of these fractures at the elbow on account of the impaired mobility which often results. The natural position of the arm in relaxation is that of flexion. He had treated these fractures in the flexed position. The extended position may cause tilting forward of the upper end of the lower fragment, or its rotation forward or hyper-extension may be caused.

Passive motion is resorted to in four or five weeks, to an extent short of causing suffering. The material used for the splint is plaster-of-Paris. He had treated many of these fractures in cases where the injury resulted from railroad accidents, where suits for damages are common, but he knew of no case where the question of defective treatment entered successfully.

Dr. John H. Packard, of Philadelphia, remarked that it was often difficult to tell the exact character of a fracture at the elbow-joint, even under the most favorable opportunities for examination. He thought that the carrying function was rarely perfectly maintained under any plan of treatment. After fracture running into the joint there is liability to the formation of adhesive lymph. He thought that passive motion should be resorted to before the organization of the adhesive lymph. He advocated treatment of these fractures in the flexed position, and described a splint of sheet zinc which he had used with satisfaction.

Dr. Charles B. Porter, of Boston, thought that the treatment advocated in the paper violated one of the first principles in the treatment of fracture, that is, to place the muscles in a state of relaxation. In the extended position the muscles which should be relaxed are not at rest. He had never seen any statistics in regard to the results of treatment of fracture in extended position, in comparison with those in the flexed position. Until these are forthcoming, the profession will be unwilling to accept this as the best method of treatment. He therefore gave his adhesion to the treatment of these fractures in flexed position rather than extended position. Before the fracture is dressed it should be adjusted under ether, and then not looked at for two or three days, and if found in position not again dressed for a week or ten days. In old fractures where there is sufficient deformity to demand osteotomy, reaction of the elbow is better, and by it a very useful arm may be secured.

Dr. J. Ford Thompson, of Washington, D C., did not approve of treating fractures of the lower end of the humerus in a right-angled position. In his treatment he adopted the plan which permitted the axes of the fragments being brought into relation with each other. This he had found to be the extended position. In two cases of compound fracture he had been unable to bring the fragments into line until the forearm was extended. The difficulty about the straight position is that it is disagreeable and uncomfortable to the patient. He considered plaster-of-Paris to be the best dressing.

Dr. A. G. Gerster, of New York, held that the bad results which are often seen after fracture of the lower end of the humerus are not necessarily due to the method of treatment. In several cases where he had had an opportunity to examine the joint, he had found that the trouble was due to the throwing out of callus at points where the callus had been stripped off. Bad results are also often due to insufficient examination. Anæsthesia is not employed, and the dislocation which may accompany the fracture is not recognized. In the treatment of the fracture, after replacing the fragments, such methods must be employed as will hold them in place. The flexed or extended position must be employed as necessary. He had found that, as a rule, the fragments were best held in place by treatment in extension. He does not employ passive motion, and considers it useless and often harmful.

Dr. Stephen H. Weeks, of Portland, Me., said that it was his custom to treat supra-condyloid fractures of the humerus in a position of flexion, but he was satisfied that satisfactory results are secured by different methods of treatment.

Dr. T. J. Dunott, of Harrisburg, thought that the manner in which the injury had been received had much to do with the ultimate result. He was inclined to think that the flexed position would give a good result in many of these fractures associated with severe injuries. He preferred to treat the arm in such a position that the radius and ulna are parallel. In many cases where great injury is done to the soft parts no splint can be applied, and under such circumstances the arm should be laid on a pillow and lead-water and laudanum applied for some days until the tumefaction goes away. If necessary, incision into the tense tissues is made.

Dr. W. H. Carmalt, of New Haven, said that in some cases the ulna acted as a wedge between the two fragments at the lower end of the humerus, forcing them apart, and reported a case which he had recently treated in the flexed position, using extension by means of weights, obtaining a satisfactory result.

Dr. J. Collins Warren, of Boston, had observed the difficulty mentioned by Dr. Carmalt, but had attributed it to drawing forward of the condyles rather than to sinking in of the ulna. Dr. Bigelow had laid down the excellent rule of going through the movements for reducing a dislocation at the elbow in these cases. In this way the danger of overlooking a dislocation is avoided, and if there is simply a fracture the manipulations mould the bone into place. The flexed position with an internal angular splint seems to be the best method.

Afternoon Session.

The Treatment of Uncomplicated Fractures of the Base of the Radius, by Dr. John B. Roberts, of Philadelphia. The following conclusions were presented:

1. Fractures of the lower end of the radius vary comparatively little in their general characteristics, because but one form is usual.

2. Muscular action has little or nothing to do with producing or maintaining the deformity.

3. Immediate reduction of the fragments is the essential of treatment.

4. Many of the splints devised for the treatment of this fracture have been constructed in ignorance of the pathology of the condition.

5. The ordinary fracture of the lower end of the radius usually requires no splint, and should be dressed with a wristlet of adhesive plaster or bandage.

6. When a splint is required, a narrow, short, dorsal splint, fixing the wrist, is all that is necessary.

7. The method of dressing here advocated is the best, because it annoys the patient as little as possible by avoiding cumbersome appliances, and permits free voluntary movements of all the finger-joints.

8. Passive motion is unnecessary until union has occurred and the dressings have been finally removed.

9. Good use of the wrist and fingers is early obtained, and the anatomical conformation is restored as well as, and perhaps better than, by other more complicated dressings.

10. Old fractures, which have been improperly treated

by omission of immediate reduction, may with considerable success be subjected to refracture at the end of six or more weeks. At later periods readjustment may be possible only by osteotomy, which is a legitimate means of treatment.

Dr. John H. Packard, of Philadelphia, had in 1879 read a paper on this subject before the American Medical Association, in which he took the ground that the great difficulty in many of these cases arose from non-reduction. If the fracture of the lower end of the radius, commonly known as Colles' fracture, is once reduced there is little tendency to reproduction of the deformity. Many physicians think that all that is necessary is to apply the proper dressing. The most important step in the treatment is reduction. He did not agree with the fifth proposition, that no splint is required. He employs an anterior splint padded to fit the curve of the radius and reaching to the ball of the thumb. The patient can use the fingers freely. In ordinary cases who will take proper care of the arm, this simple splint suffices.

Dr. Charles B. Porter, of Boston, emphasized the necessity for complete anæsthesia, then complete reduction and breaking up of the impaction, and then the application of a posterior and anterior splint; after a week or ten days, he allows motion of the fingers, and in two weeks motion at the wrist. He considers passive motion unnecessary except in old people, where there is a rheumatic or gouty tendency.

Dr. J. Ford Thompson, of Washington, dwelt upon the disastrous results that often followed failure to reduce the displacement, or the use of improper dressings. After reduction of the fragments he applies an anterior and posterior splint secured lightly to the arm. He had not found it necessary, as a rule, to use ether to accomplish reduction. In cases where there was severe pain following the application of the ordinary splint, instant relief followed the application of a plastic splint, the hand being carried well to the ulna side. In several cases where the hands were useless from the inflammation of the sheaths of the tendons, he had tried to break these up under repeated administrations of anæsthetics, but the results had not been very marked.

Dr. Joseph Ransohoff, of Cincinnati, said that in some cases the reduction could not be effected so readily as had been described. He had had three or four cases in which extension would not overcome the difficulty, and in such cases hyper-extension has been resorted to. In the treatment he is partial to the Levis splint. After a week or ten days passive motion is resorted to.

Dr. Charles B. Nancrede, of Ann Arbor, called attention to the fact that a certain amount of the bone-tissue at the seat of fracture was destroyed, so that some deformity will necessarily follow. Reduction is the most important measure in the treatment. The fragments are then to be held in place by suitable apparatus.

Fibroid Tumors of the Uterus.—Dr. John Homans, of Boston, read this paper. Fibroid tumors were defined as aggregations of normal uterine tissues in abnormal situations and masses. They may cause symmetrical or more or less one sided enlargement; they may be in the walls of the uterus, or protrude toward its outside or toward its inner cavity; they may be incorporated with the uterus or connected with it by a broad attachment, or by a pedicle, or they may be entirely separated from it and get their nourishment from the vessels of the omentum or mesentery. They may be dense, œdematous, or filled with lymph-spaces, or they may in very rare instances be fibro-cystic. It is probable that a certain number of the tumors which have been described as fibro-cystic belong to the class of fibroids with dilated lymph-spaces. True fibro cysts are very rare.

In size these tumors vary from that of a mere dot to masses weighing fifty or more pounds. Their growth is slow. They are of common occurrence. In the past fifteen years the author had seen about five hundred and twenty fibroid tumors.

Operations to relieve women with fibroid tumors are rarely necessary. The writer had operated on only sixty of these five hundred and twenty cases, eleven per cent. The conditions which should guide us in recommending removal of the tumors are: When they threaten life by hemorrhage; when they are unbearable from their weight or the inconvenience they cause; when in a young woman they cause distress and shame from the alteration in her figure; when they cause much pain; when they cause serious obstruction of the circulation, or interfere with the action of the digestive or eliminative organs; when they cause obstruction of the bowels, or when their pedicles have become twisted and sometimes the whole uterus becomes twisted on its axis.

Death by hemorrhage is rare. The speaker knew of only three instances. In fibroids complicating pregnancy, the tumor may threaten to render delivery impossible, but nature will generally get the obstruction out of the way if you give her a chance.

The solid fibroid tumors rarely have adhesions, and are removed without much difficulty. Of fibro-cystic tumors the speaker had met with only eight in the five hundred and twenty cases. None of these were successfully removed. One woman recovered from an incomplete operation. The others all died. The author had reported an extraordinary case of twisting of the uterus as the pedicle of a large fibroid tumor. The uterus was twisted one and a half time on its axis. The case was fatal, no operation having been done.

The natural history of ninety per cent. of fibroid tumors is to remain stationary after reaching a certain size, and after the menopause to become cretaceous and atrophied. About ten per cent. require removal. The average age at which the speaker had operated was thirty-nine years.

Treatment by ergot alone is usually ineffective; combined with curetting it helps to stop hemorrhage. Treatment by high doses of electricity à la Apostoli sometimes stops hemorrhage, almost always relieves pain, and gives strength, but rarely diminishes the size of the tumor. In four cases the speaker had practised removal of the ovaries for the cure of fibroid tumors. In one woman, aged forty-four, the tumor disappeared in a few weeks and menstruation at once ceased. In another, aged thirty-five, the catamenia gradually ceased after three years, and the tumor remained about the same. In another, aged thirty-four, there was irregularly recurrent bleeding for eight months after operation. A fourth case, aged thirty-six, was not at all relieved by the operation. He was inclined to regard this method as unreliable.

Curetting often cures the hemorrhage completely. This is followed by the application of tincture of iodine. The surgical treatment at the present time is almost wholly by removal of the tumor with or without the uterus. If the tumor has been protruded into the cavity of the uterus it should be enucleated and removed under careful antisepsis. Other tumors requiring removal must be removed by abdominal section. The operation may be finished in several ways. Sometimes the wound in the uterus can be closed by stitches, or the pedicle may be treated by the extra-peritoneal method after constriction with the serre-nœud. Sometimes the stump is simply tied as is the pedicle of an ovarian tumor and then dropped. Sometimes the stump is turned into the vagina. All the different methods depend for their fundamental process on asepsis and on securing the vessels of the broad ligament, no matter in what way the pedicle or neck or body of the uterus is ultimately disposed of.

The condition of most patients from whom fibroid tumors have been removed is very comfortable. Some suffer from "hot flashes." Others grow extremely fat. A certain proportion, particularly those in whom the pedicle has been treated extra-peritoneally, suffer from ventral hernia. Sometimes the bladder is cut off by the wire

écraseur, but in the only case he had seen the bladder healed in a few weeks by keeping it drained, and during the ten years that have elapsed since the operation, the bladder has been perfectly normal.

The length of the incision does not complicate the operation, provided there are no adhesions. Very rarely insanity follows the removal of a fibroid, as it does other surgical operations. The author had never seen this complication follow hysterectomy. He had seen two cases of tetanus in the cases of other operators, but had had no case himself after hysterectomy. He had had one case follow ovariotomy. He invariably sees that patients who have recovered from abdominal hysterectomy are fitted with a firm abdominal supporter, and impresses upon them the necessity of being careful about carrying heavy loads or straining themselves.

Dr. A. Vander Veer, of Albany, said that in looking over his notes, he had found that the age from thirty to forty-eight years has been most prolific in the development of these tumors. The hemorrhage, which is usually the symptom that attracts the attention of the patient, is dependent not so much upon the size of the tumor as upon its location. The hope that after the menopause is reached the fibroid will subside is not always verified. In some cases the tumor seems to take on a more active growth at that time. As to treatment, curetting and packing with iodoform gauze will often stop bleeding; where this fails, in small fibroids, oöphorectomy invariably cures except in soft myomas. The danger in treatment rests with the size of the tumor. It is the large ones that give the mortality after operation.

Dr. J. Ewing Mears, of Philadelphia, held that where the only reason for the removal of the tumor was the large size of the abdomen, giving rise to unpleasant remarks, we should not be guided by the patient's desire that the operation should be done. He related the case of an unmarried woman, who desired the growth removed on account of the distention of the abdomen which it produced. He refused, and she passed into the hands of another practitioner, who did operate, the patient dying five hours later. Dr. Mears divided those cases requiring operation into two classes. We are justified in operating where the hemorrhage endangers life; second, we are justified in operating where the pressure symptoms are such as to make life unbearable. There are, however, many cases in which under palliative treatment life may be prolonged, the patient rendered comfortable, and be able to enjoy life. He had found electricity palliative, but not curative. The tumor is sometimes reduced in size.

Dr. George W. Gay, of Boston, spoke of the treatment of fibro-cystic tumors and referred to the use of tapping. He reported one case in which he began tapping in 1879, repeating it every two or three weeks for four years; ninety tappings in all were made. The patient is now in good health, with a large abdomen, but has not been tapped for years. Other similar cases were reported.

Dr. Robert Abbe, of New York, referred to the value of the Trendelenburg posture and the early securing of the arterial supply of the uterus in these operations. He was rather surprised at Dr. Homans's assurance that death from hemorrhage was rare. He had thought the contrary. It is the symptom that frightens the patient and alarms the surgeon. He had had fair success with electricity, and would advise it in many cases. The tumor will grow, but the hemorrhage will cease.

Dr. John Homans, of Boston, said that the use of strong currents of electricity to the interior of the uterus caused some change to the mucous membrane, checking bleeding, but it did not prevent conception. It was his custom to advise patients with fibroid tumors not to marry. Cases bearing upon this point were related.

The Association then adjoined until Wednesday morning.

Second Day, Wednesday, June 1st—Morning Session.

The morning session was given up to a visit to the Massachusetts General Hospital, where a number of interesting cases were shown and the methods of work demonstrated.

Afternoon Session.

Surgery of the Tongue.—Dr. N. P. Dandridge, of Cincinnati, read a paper on this subject. The paper was confined to a consideration of operative procedures in malignant disease. Our knowledge of lingual cancer was first reviewed. As a rule it appears in the form of epithelioma. It runs its course in about a year and a half. In many cases it develops from an indifferent lesion which has been subjected to continued irritation. Neighboring glands are usually affected, and this may occur within three months, or not for six or nine months, after the appearance of the disease. In ulcerated epithelioma the diagnosis will most often hesitate between that and tubercular and syphilitic ulcer.

The history of operating for cancer of the tongue was then considered, and the author expressed his agreement with the following propositions laid down by Treves: 1. The organ should be removed by cutting with the scissors or knife. 2. The removal should, as a general rule, be effected through the mouth. 3. Every means should be taken to reduce the hemorrhage to a minimum. 4. When the floor of the mouth is involved, or the glands extensively involved, the incision should be carried out through the neck.

The following methods were then described in detail, Whitehead's, Morant Baker's, Kocher's, and Volkmann's.

Whitehead's Method.—In this operation a gag is used, care being taken to avoid pressing back the jaw and impeding respiration. The patient is in a sitting position. A ligature is passed through the anterior part of the tongue, and scissors are used for the section. If the frænum and the anterior pillars of the fauces are completely divided, the tongue can be drawn freely from the mouth. The organ is then separated by free cuts with the scissors until the main artery is reached. This is seized with forceps before division. Before completely severing the tongue, it is desirable to pass a loop of silk through the glosso-epiglottidean fold, in case it may become necessary to make traction on the posterior floor of the mouth. The parts are then rendered as aseptic as possible by swabbing over with 1 to 1,000 biniodide of mercury solution, and painted with iodoform styptic solution; Friar's balsam, in which the spirits are substituted for a concentrated solution of iodoform in ether, one part in ten of turpentine having been added to the ether. This varnish is repeated daily. The patient is not kept in bed, but encouraged to go in the open air. Whitehead has reported 104 cases of total removal of the tongue by this method, with 20 deaths or $19\frac{20}{100}$ per cent. Of 61 patients, 15 survived the operation one year; 4, two years; 2, three years; 4, five years, and 1, six years.

Baker's Operation.—In this operation two threads are passed half an inch from the median line of the tongue on each side. The attachments of the tongue on the side are divided with scissors, keeping close to the lower jaw. The mucous membrane is next divided along the median line, and the two halves of the tongue separated by the finger. The diseased half of the tongue is then removed with the écraseur. After this, glands should be searched for and removed either from the floor of the mouth or by external incision.

Kocher's Method.—Kocher's operation has been commended in cases in which the floor of the mouth and the submaxillary glands are involved, but is too serious an operation for cases where the disease is confined to the tongue. Tracheotomy is first done, and the fauces plugged. An incision is then made along the anterior

border of the sterno-mastoid muscle. From the first, an incision is made from the middle of the sterno-mastoid muscle to the hyoid bone, and along the anterior border of the digastric to the jaw. The flap is turned up, and the facial artery and vein and the lingual artery tied. The submaxillary fossa is then completely cleaned out. The attachments of the tongue are now divided, and it is drawn through the opening and removed, either in part or in whole, by scissors or galvano-cautery. If the whole tongue is removed, the lingual artery of the opposite side must be ligated through a separate incision. The tracheotomy tube is allowed to remain, and the wound is kept packed with gauze soaked in carbolic acid solution. This is changed twice a day, at which times food is given. In fourteen cases thus operated on there was only one death.

Volkmann's Method.—Volkmann's method has been attended with extraordinary success, there having been only two deaths in ninety-one operations. The patient is seated in a chair. If the tongue can be brought forward a resection is made with knife or scissors, and the mucous membrane brought together, or if a strip of healthy tongue is left, it is turned around so as to make a short, broad organ. If the disease is too extensive to admit of this method, a traction thread is passed through the tongue, and it is drawn forward. The canine or first molar tooth is extracted and incision made downward from the corner of the mouth, and the lower jaw divided. The portions of bone are separated and the attachments of the tongue divided. The cut surfaces are covered with mucous membrane and the bone wired. A drainage-tube is placed in the tonsillar fossa and brought out at the lower portion of the incision.

In the after-treatment of removal of the tongue for cancer the three great factors are, 1st, let the patient be well fed; 2d, let all discharges escape from the mouth; 3d, keep the cavity of the mouth sweet and clean.

The author next referred to the palliative treatment to be employed in cases where operation was not indicated, or where the patient refused surgical interference. For the pain a powder consisting of iodoform, one grain, morphine, one-sixth to one-half a grain, borax, three grains, has been recommended, applied directly to the painful spot. Cocaine has naturally been resorted to, either by application to the surface or by hypodermic injection; but there is danger of the establishment of the cocaine habit. The excision of a portion of the lingual nerve was highly recommended, but the relief thus afforded may be only temporary. For the relief of salivation and fetor various antiseptic mouth-washes may be employed. Where there is difficulty in swallowing on account of the pain, relief may be afforded by painting the surface freely with cocaine just before the administration of food, or a short rubber tube may be passed into the œsophagus.

The following conclusions were considered justified:

1. Sufficient experience has been accumulated to show that the removal of cancer of the tongue prolongs life and adds to the comfort of the patient, and further affords a reasonable hope of a permanent cure.

2. All operations should be preceded by an effort to secure thorough disinfection of the mouth and teeth.

3. In the treatment of continued ulcers and sores on the tongue, caustics are to be avoided and all sources of irritation removed.

4. Persistent sores on the tongue should be freely removed by knife or scissors if they resist treatment.

5. When the disease is confined to the tongue, Whitehead's operation should be employed for its removal.

6. In this operation the advantage of preliminary ligation of the lingual artery is not definitely settled, but the weight of authority is against its necessity.

7. The advantage of leaving one-half the tongue, in unilateral disease, must be considered undetermined, but the weight of positive experience is in its favor. In splitting the tongue into lateral halves, Baker's method of tearing through the raphe should always be employed.

8. A preliminary tracheotomy adds an unnecessary element of danger in the removal of the tongue in ordinary cases.

9. When the floor of the mouth has become involved or the glands are enlarged, Kocher's operation should be employed, omitting the spray and preliminary tracheotomy.

10. Removal of the glands by a separate incision after the removal of the tongue must be considered insufficient.

11. Volkmann's method still rests on individual experience. Its just value cannot be determined until it has been subjected to trial by a number of surgeons.

12. Thorough and complete removal should be the aim of all operations, whether for limited or extensive disease.

13. By whatever method the tongue is removed, the patient should be up and out of bed at the earliest possible moment, and should be generously fed.

Dr. D. W. Cheever, of Boston, referred to the question of diagnosis of ulcers of the tongue. In the first place we have dyspeptic ulcers. These appear in successive crops. They are not indurated and can be made to heal by simple treatment. Secondly, we have the syphilitic ulcers. Previous history is at times of service. In doubtful cases two weeks of anti-syphilitic treatment should be employed. Third, lupus or tubercular disease; this is not so common as cancer. The test of the examination for the bacillus is not always successful. The tubercular ulcers form and reform; some heal and leave scars. Cancer does not heal, but goes on extending. In lupus the sublingual and submaxillary glands are early infected. True cancer is almost always at the side of the tongue; the infection of the glands is usually speedy.

While he advised removal of enlarged glands he did not think that the neck should be treated as the axilla. As to duration, he thought that malignant affections of the mucous membrane are more speedy in their recurrence than malignant affections in the skin and glandular structures. In cancer of the tongue the disease, as a rule, recurs in four to six months. In simple cancer of the tongue without gland involvement, preliminary tracheotomy is not needed. He operates with the patient in the sitting position, and not thoroughly etherized. He had never tied the lingual artery for cancer. The partial amputation of the tongue where the disease is limited, seems to have been as successful as the total removal. Recurrence is almost always in the glands, and rarely in the stump. Reference was also made to the remarkable recovery of the power of talking in cases where the tongue was completely removed.

Dr. L. McLane Tiffany, of Baltimore, said that in considering the operative interference we should distinguish between cases where the disease involved the anterior portion of the tongue and where the disease has begun more or less posteriorly, and there is glandular involvement. In the latter case he prefers division of the lower jaw, either at the symphysis or at the side. He thought it wise to remove the glands beneath the tongue, even if not enlarged. In this way we get rid of one of the routes of systemic infection. Where the posterior portion of the tongue is involved, permanent recovery is rare; where the glands are involved, it is still more rare. He had obtained his best results where he had divided the jaw and secured drainage from below. The incision is not closed, and ample opportunity for drainage is provided. The operation is done with the patient on the side and the head near the edge of the table, full anæsthesia with chloroform being employed. Where the tongue is excised for tubercular ulceration, the ulcer rarely recurs, although the general tubercular disease may progress.

Dr. T. F. Prewitt, of St. Louis, remarked that the selection of the operation depended largely upon the ex-

tent and location of the disease of the tongue; where the cancer is limited to the tongue an operation through the mouth is sufficient. If the floor of the mouth be involved, and the disease extend out to the bones, something more is needed. In one or two instances he had resected portions of the jaw. He did not think that the primary hemorrhage was to be dreaded, but he had seen death from secondary hemorrhage in a case of diseased arteries.

Dr. W. H. Carmalt, of Philadelphia, had found a great deal of advantage from preliminary tracheotomy. The most frequent cause of death after operation is septic pneumonia from the inhalation of infective material. Tracheotomy not only facilitates operation, but it obviates the danger of septic pneumonia. In the last case he had operated, doing tracheotomy and packing the fauces, the patient did well. At the end of four days he removed the tracheal tube and allowed the patient to breathe by the mouth. The next day the temperature was up to 102° F. The tube was immediately reintroduced and the fauces packed, and in twenty-four hours the temperature was again normal. In cases where the glands are involved, he advised the Kocher operation. In regard to after-treatment, he had found that patients bear the presence of the œsophageal tube better than its reintroduction.

Dr. R. F. Weir, of New York, had removed the tongue five times by the Whitehead operation, and five times by the Kocher operation, and had removed one-half the tongue ten times by Whitehead's operation. Where the floor of the mouth or the glands are involved he prefers Kocher's operation. He considered it good surgery, where there were signs of glandular enlargement in the submaxillary space, to cut down in front of and behind the sterno-mastoid muscle and examine the condition of the lymphatic glands in this situation. In the Kocher operation he prefers tracheotomy, and does it a few days before if there is sufficient time. He considers it a great advantage both at the time of operation and afterward.

Dr. A. G. Gerster, of New York, had extirpated the tongue in various ways in nineteen cases. He thought that the more thorough and radical the operation, the better were the results. He advocated removal of the affected glands, and the use of tracheotomy. This enables the operation to be more thoroughly done, and with more comfort to the surgeon and less danger to the patient. In this region, as in every other region of the body, thorough operation requires thorough anæsthesia.

Dr. T. J. Dunott, of Harrisburg, reported a case where the tongue was greatly enlarged and protruded from the mouth. The operation was done several years ago, and the patient is still living and well.

Dr. Joseph Ransohoff, of Cincinnati, reported one case on which he operated by the Mordant-Baker method, four and a half years ago, and there had been no relapse. In other cases on which he had operated he had not obtained the same success. In every case where he did not do a Kocher operation he made an incision in the submaxillary triangle, in order to put in a large drainage tube reaching to the floor of the mouth. This opening gives an opportunity for the examination of the glands. If there is enlargement the gland can be turned out or the incision enlarged, if necessary.

Conditions Demanding Excision of the Globe of the Eye.—Dr. W. H. Carmalt, of New Haven, Conn., read a paper on this subject. As a rule, the question of the propriety of enucleating an eye will be referred to the specialist, but there are cases of emergency in which the general surgeon is called upon to act promptly. In the consideration of this subject we are at once confronted with it from two different stand-points, according as we have to deal with blind eyes or with those in which there is a more or less useful degree of vision.

In the case of blind eyes, the objections to the operation are two: 1, The danger of the operation *per se*, and 2, the cosmetic appearance. Meningitis has occurred in some cases operated on in the acute stage of suppurative panophthalmitis. In these cases the removal should be made as soon as the evidences of suppuration are unmistakable. In cases of lacerated or penetrating wounds with loss of vision, the operation is better done before suppuration occurs, or as soon as the evidences of suppuration are sufficiently plain.

There is no one condition for which eyes are so frequently excised as in sympathetic ophthalmitis (threatened or actual). The pathology of the sympathetic process is still a matter of controversy. In a case presenting the irritative symptoms indicating the beginning of sympathetic ophthalmitis, with the other eye lost from injury, or certain forms of disease yet to be mentioned, it is the duty of the surgeon to advise in the most unqualified manner the enucleation of the blind eye. The irritative stage is usually short. It is more or less rapidly followed by diminution of vision, due to an organic lesion. In the acutely inflammatory stages of the sympathetic disease, the removal of the "excitor" is not so beneficial to the "sympathysor," and may be harmful, adding fuel to an already flaming fire. In these cases the operation should be postponed until the active process is subdued. It must also be remembered that in a small number (perhaps about ten per cent.) the sympathetic inflammation may come on after the removal of the excitor, and in about two per cent. it has been thought to have been the result of operation. The conditions liable to give rise to sympathetic ophthalmitis are—1, injuries; 2, diseases.

Injuries.—a. Lacerating or perforating wounds, so severe that the result will inevitably be atrophy of the globe. *b.* The lodgement of a foreign body in the interior of the globe. *c.* A penetrating wound involving the ciliary region.

Diseases.—a. Recurring or chronic irido-choroiditis from whatever cause. *b.* Atrophy of globe following purulent keratitis, or panophthalmitis, or in which ossific degeneration of the retina has taken place. *c.* Atrophy of the globe from any cause, with painful ciliary region.

Time does not confer immunity against sympathetic disease. There is considerable difference as to liability to the disease in the various injuries and diseases. This sequence is more frequent after injuries than after non-traumatic diseases, and of injuries, nothing is so potent as the lodgement of a foreign body in the eye.

The pain which comes from the intra-ocular pressure of a chronic glaucomatous degeneration is frequently so excessive as to justify the removal of the offending organ, other means of treatment having failed.

Various diseases of the eye leave the organ in conditions so inconvenient or repulsive in appearance that the surgeon's aid is sought for purely cosmetic purposes. Are there, however, no procedures that may be substituted and avoid so severe a mutilation? In the earlier days of ophthalmology abscission of the anterior segment of the globe was often practised. In this operation more or less evisceration of the contents of the globe takes place. As a matter of fact the result is about the same, as often enucleation and sympathetic ophthalmia may follow the operation. The opinion of the author was decidedly against such risky procedures; enucleation of the misshapen eye, with the introduction of an artificial eye, is the only admissible operation. The modern expedient of tattooing a white cicatrix of the cornea without staphyloma has resulted in sympathetic disease.

In the enucleation of blind eyes that are the seat of phosphenes, but like many operations undertaken to relieve a symptom of nerve irritation, its utility is doubtful. In regard to the enucleation of eyes only partially blind, it goes without saying that a condition of things which can allow it to be seriously contemplated must apply with greater force to eyes already blind. The chances of accident or independent disease to the remaining eye are sufficiently great to justify the statement that nothing short of the certainty of ultimate blindness to both, or of death, can permit one to consider such a procedure.

Most of the intra-ocular tumors are sufficiently dangerous to life to demand the removal of the organ in which they are contained, as the only hope that can be entertained of successfully combating their encroachment. They are of two classes, the granulomata and the sarcomata. The extra-ocular growths are of greater variety of histological structure. In sarcomata of the orbit removal of the globe is often required, even when not implicated in the disease.

Should an eye which retains an appreciable degree of vision be removed in order to arrest a threatened or prospective attack of sympathetic disease in the fellow? It is certainly unjustifiable to remove an injured but still seeing eye, though it may be an excitor of sympathetic disease. The result of the operation has not been sufficiently successful in averting the progress of the malady, after it has been begun, to warrant its recommendation. The only condition in which it was considered justifiable to remove a still seeing eye for sympathetic disease is where a foreign body remains in the eye. In these cases sympathetic disease is very apt to follow.

Election of Officers.—The following officers were elected: *President*, Dr. N. Senn, of Chicago; *Vice-Presidents*, Dr. W. W. Keen, of Philadelphia, and Dr. Charles B. Porter, of Boston; *Secretary*, Dr. J. R. Weist, of Richmond, Ind.; *Treasurer*, Dr. John B. Roberts, of Philadelphia; *Recorder*, Dr. J. Ewing Mears, of Philadelphia; *Members of Council*, Dr. Roswell Park, of Buffalo, and Dr. R. F. Weir, of New York; *Member of the Executive Committee* of the Congress of American Physicians and Surgeons, Dr. R. McLane Tiffany, of Baltimore; *Alternate*, Dr. James McCann, of Pittsburg.

The following were elected to membership: Dr. John B. Deaver, of Philadelphia; Dr. Frederick H. Gerrish, of Portland, Me.; Dr. William S. Halstead, of Baltimore, Md.; Dr. Charles McBurney, of New York, and Dr. Henry R. Wharton, of Philadelphia.

It was decided to hold the next meeting in Buffalo, N. Y., in May, 1893, and Dr. Roswell Park was elected Chairman of the Committee of Arrangements.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

ENTERECTOMY BY A NOVEL METHOD—SPONTANEOUS CURE OF FEMORAL ANEURISMS—HÆMOPTYSIS IN RENAL CIRRHOSIS—MAMMARY ABSCESS AND TUBERCULOSIS—INDIGO IN THE URINE—THE RECENT ELECTION AT THE PATHOLOGICAL SOCIETY—THE DECREASE OF INFLUENZA—CONTINUED INCREASE OF SMALL-POX—THE LONDON COUNTY COUNCIL AND POST-MORTEM EXAMINATIONS.

London, May 21, 1892.

At the last meeting of the Clinical Society, Mr. F. Paul, of Liverpool, gave an account of a case in which he had performed enterectomy in a novel manner. The patient was a woman, aged thirty-seven, who had been suffering for six days from an unrelieved strangulated hernia. The bowel had to be excised, as it was sloughing. Mr. Paul employed the following procedure in order to reunite it: A bone tube armed with a traction needle was so sewn into the upper end. The traction thread was then passed through the wall of the lower end, about three inches down, and the two ends were lightly attached to each other. An assistant then held the traction thread while the operator invaginated the bowel over the tube so as to completely cover the cut; the tube was retained in this position with four Lembert sutures, and the traction thread drawn tight and cut off short. The patient was fed freely with liquid nourishment from the first; bread and milk were given on the sixth day, and meat on the fourteenth day. The bowels were well moved by glycerine enemata on the eighth day. The patient was convalescent at the end of a month, and was now quite well and the bowels quite natural. Mr. Howard Marsh remarked that Mr. Paul's method was so simple that any surgeon could practise it. Mr. Jessett said he thought puncture of the lower segment of bowel was dangerous. All operations that comprised invagination were difficult where the intestine was greatly distended. He favored lateral approximation and had always found it successful. Dr. Robinson's suggestion to use a rubber tube was risky, as such tube could not be absorbed as bone could. Mr. Paul replied that he had never witnessed any ill effects follow puncture of the intestinal wall with an ordinary small needle and thread. He did not consider lateral approximation was likely to be satisfactory.

At the same meeting of the society Mr. Howard Marsh related a case in which spontaneous cure of femoral aneurisms occurred. The patient was a man, aged forty-three, who was admitted into hospital with a well-marked aneurism in Hunter's canal as large as a small orange. The skin over the tumor was hot and suffused, the superficial veins distended, the patient's temperature 100.2° F., and there was considerable pain. On the following day pulsation in the tumor had ceased, and the tumor had become firm and hard except at its central part. The swelling gradually lessened, and in twelve weeks the patient was discharged cured. In a few months he was readmitted with a second and smaller aneurism in the upper part of Hunter's canal. After one day's rest in bed, however, this aneurism also was found to be free from pulsation and apparently solid; it slowly disappeared in time. Mr. Marsh thought that in the case of the first aneurism coagulation in the sac was induced by inflammation of the parts around, or possibly by displacement of a portion of clot; he thought the latter was perhaps the manner in which the second aneurism was cured.

Dr. Francis Hawkins then gave an account of a case of renal cirrhosis in which profuse hæmoptysis occurred, and symptoms simulating those of tuberculosis. The heart was much hypertrophied and there was general arterio-sclerosis. There was slight dulness over the left infra-clavicular region, and decided dulness, with moist râles, over the left infra-scapular region. The urine contained albumin and hyaline casts, and micturition was frequent. As the hæmoptysis was associated with increased arterial tension, iodide of potassium was given with beneficial results. Subsequently the case passed into other hands, and ergot was given, which increased the bleeding. The diagnosis of renal disease was verified at the post-mortem examination; the left lung was then found to be carnified at its base, emphysematous and œdematous at its apex. The right lung was emphysematous, congested, and œdematous. Dr. Hawkins drew attention to the fact that hæmoptysis might occur as a symptom in renal disease, and that a hypertrophied heart might produce physical signs in the left lung which might be mistaken for those of tuberculosis. He also pointed out that ergot often produced an increase rather than a diminution of hæmoptysis.

Mr. Arbuthnot Lane made a short communication in which he drew attention to the frequent association between chronic mammary abscess in women and a history of tuberculosis, or the presence of tuberculous disease in other organs. Though such abscesses were not usually associated with tuberculous disease of the axillary glands, he nevertheless regarded them as being of tuberculous nature.

At the last meeting of the Pathological Society, Dr. Ord gave an account of a case in which a deposit of indigo occurred in the urine. The patient had suffered for ten years with symptoms of prostatic enlargement. The urine was alkaline and offensive, and contained a number of flaky masses; under the microscope these were found to be altered mucus and embedded in them were a number of dark-blue bodies, apparently composed of some crystalline material partly stained by indigo, partly having indigo deposited on them. He considered these to be

either urate or phosphate. He knew of no artificial method whereby indican present in alkaline urine might be decomposed so as to form indigo blue without inducing an acid reaction. He thought the form of the indigo was determined by the form of the substance on which it had been deposited. Dr. Ord then described the ordinary method of obtaining indigo from urine either in the form of a solution in chloroform, or in a film deposited on the surface of the fluid. If a solution of uric acid were previously added to the urine, crystals of uric acid partly stained and partly incrusted by indigo were found at the bottom of the fluid. Epithelial cells, yeast cells, and rod-shaped bodies resembling bacteria were also found similarly stained, and occasionally hedgehog crystals presumably consisting of uric acid were found deeply colored. Dr. Ord suggested that possibly nascent indigo might be of use in the staining of bacteria.

At the same meeting of the Society the various officers for the ensuing year were elected. An unexpected incident occurred to vary the usual tameness of the proceedings. The method in vogue at this and the other medical societies of appointing the office bearers is simplicity itself. The outgoing Council nominate their successors, and the members pass the list as a mere matter of form. On the present occasion, however, another secretary was substituted for one of those chosen by the Council, and loud are the murmurs in consequence. Many members did not vote at all, regarding the election as a mere formality. I understand that a comparatively small number of members were able, by substituting the name of another gentleman on their ballot-paper, to secure his election. An appointment by a minority cannot, of course, be regarded as an ideal method, but there is certainly another side to the question besides that presented by those who complain of the recent incident, and that is, whether some radical alteration in the method of appointing office-bearers is not desirable? Why should the nomination be left to the Council, and, if that is to continue, why should not several names be selected for each appointment and the majority of votes decide the result?

In my last letter I stated that no death from influenza had taken place within the metropolitan area during the preceding week, and that the epidemic had practically disappeared. I find that I was in error. The epidemic has, it is true, almost disappeared, but some deaths from it still occur weekly, and ten deaths from influenza were registered in London during the week in question.

Small-pox is still steadily increasing, both in London and the provinces. Further facilities for isolating cases in the earlier stages are urgently needed, at any rate in the poorer districts.

Is it any part of the duty of a medical man to cleanse a corpse before or after making a post-mortem examination? The London County Council think not. At any rate they have refused to allow any payments for such cleansings. At a recent inquest the medical man who made the post-mortem drew attention to the state of the body, and the coroner explained that his officer had not cleansed the body because he could not be paid. The jury expressed an opinion that the County Council should pay for such cleansing.

Dermatological Prizes.—The prize which was offered in 1891, by Dr. Unna, of Hamburg, for the best essay on "The Topography of the Elastic Tissue in the Skin of Adults," has been awarded to Dr. Zenthöfer, of Stallupönen. *The British Medical Journal* announces that the subject of the prize of $75, for 1892, which is open to all competitors without restriction, is "The Wasting and Regeneration of the Elastic Tissue of the Skin under Different Pathological Conditions." The judges are Professors Klebs and Hoyer. Essays must be sent in by the beginning of December, 1892, to Leopold Voss, publisher, Hohe Bleichen 18, Hamburg, from whom any further information that is required may be obtained.

OUR BERLIN LETTER.

THE SEVERE FORMS OF ANÆMIA—THE IMMUNITY QUESTION—CIRRHOSIS OF THE LIVER—HYPNOTISM, SUGGESTIONS AND THERAPEUTICS—A NEW BREAD FOR DIABETICS—THE ELEVENTH CONGRESS FOR INTERNAL MEDICINE.

BERLIN, May 15, 1892.

Of all scientific congresses which have taken place in our congressional century, the one for "Internal Medicine" has proven the most fruitful and profitable, inasmuch as such great and shining lights of medicine as Frerichs, Kussmaul, Gerhard, Liebermeister, and Leyden, stood by its cradle.

This Congress, which lasted from April 20th to 23d, in Leipsic, had some very important and interesting lectures, from which we will only give sketches of the most important.

Firstly, we may mention the "Severe Forms of Anæmia," by Professor Birch-Hirshfeld, Leipsic, and Professor Ehrlich, Berlin.

Birch-Hirshfeld maintained that a vast difference should be made between secondary anæmias and chlorosis, on the one hand, and the really severer forms of pernicious anæmia, on the other hand. The latter (pernicious anæmia) is characterized by the lessening of the number and degeneration of the red blood-corpuscles, with resulting breaking-down in the tissue (fatty degeneration), increased excretion of uric acid or urea, and peptonuria.

Decrease of the red blood-cells is probably induced because of the immense breaking-down and destruction of the cells, in which there is an insufficient compensatory regeneration from the blood-forming tissues, especially those forming the bone and marrow elements.

As a reason for this breaking down of the blood corpuscles, there may be several detrimental causes, which, by decomposing the blood-plasma, or by direct action on the blood-corpuscles, destroy the normal equilibrium.

The following etiological factors might be summarized: 1. Excessive loss of blood. 2. Disturbances of digestion. 3. Parasites (anchylostomom duodenale, bothriocephalus latus, triocephalus). 4. Gravidity and the puerperium. 5. Chronic infectious diseases, *e.g.* (malaria and syphilis). 6. Toxic processes.

In regard to the therapeutics the speaker mentioned that arsenic was of undoubted value in a given number of cases, and transfusion would produce palliative results in a certain class of cases. The main sides of the treatment depended, however, on the dietetic and climatic management.

The second speaker, Professor Ehrlich, mentioned the anomalies of the blood in the living body. From the red blood-corpuscles the regenerative and the degenerative forms can be differentiated. To the latter belong the various cracked forms (Schistocyten or Poikilocyten), as also those forms in which different changes in the structure and chemical composition take place within the cell-body of the red-blood elements. The latter one is characterized by the difficulty with which it stains; the former, by the appearance of strange organisms within the centre of the cell-body, so-called hæmoglobinæmic inside bodies. Here we have to deal with a slow loss of the coloring matter of the blood until we have a very pale blood-film left, so-called shadows ("Schatten").

The regenerative forms are nucleated red blood-corpuscles, of which we can distinguish two forms, a smaller (normoblasts), and a very large form (megaloblasts), with very weak staining nucleus.

The first are found in the normal state in the blood-forming organs, and are found in the circulation blood of adults only by changes in the blood during poisoning (certain kinds only), or by simple secondary anæmias only.

The megaloblasts are held by Ehrlich to be the embryonal formation types of the red blood-corpuscles, and

appear as regenerative forms only in the malignant forms of pernicious anæmias and then in very small numbers in the blood. They are a characteristic sign of a severe form of disease.

In the bone-marrow we find a compensatory rebuilding process in the severer anæmias (red marrow), which is, however, entirely absent in the severe forms of pernicious anæmias.

The leucocytosis, the speaker believes to be due to the emigration of the polynuclear cells of the bone marrow. The discussion which followed was participated in by Trojé (Berlin), Fürbringer (Berlin), Klebs (Zürich), and Dehio (Dorpat).

The second important point for discussion was the interesting "immunity question." Professor Emmerich (München) believed that a certain portion of the blood and tissues of immune individuals (Immunproteine) possess the property of rendering immune healthy bodies into which they are introduced, healing sick bodies into which they are brought, by the action which they have on the already-formed toxine, by neutralizing the same, and by destroying all the micro-organisms.

Professor Hüppe (Prag) referred to the immune substance produced from the bacteria forming toxines, but believed that the cells of the body and organism produced immune products.

Professor Buchner (München) remarked that blood serum contained prophylactic substances against bacteria so long as it contains snfficient salts, *e.g.*, chloride of sodium, chlorate of potassium, and chloride of ammonium.

Dr. Klemperer makes a strong difference between inoculation with serum of already immune animals (whereby the immune action occurs very quickly) and between inoculation with diluted clear cultures whereby the immune-rendering substance, which is much slower produced and effected, remains. For the treatment of already infected animals or human beings, the much-quicker-acting serum therapeusis would be called for. With this supposition, there was proven that in twenty cases of inflammation of the lungs the serum therapeusis caused a very mild course of the disease. The speaker believed that poisons generated by the infectious diseases were paralyzed by the serum, whereas the bacteria were, by the constantly arising leucocytosis, enclosed in the white blood-cells and destroyed therein (phagocytosis).

Dr. Wassermann (Berlin) differentiated between immune-rendering and poison-fastening, or, as he terms them (Immunisirung und Giftfestigung). The former is a protection against the development and growth of the bacteria, whereas in the latter a paralysis of the toxines is produced by the bacteria by means of the serum, therapeutics, or inoculation of the thymus gland extract.

If we inject only the substances produced by the bacteria, which through acute leucocytosis contain the antitoxine, we receive an immunity, but a very slow one, and also a very unreliable one.

Finally, Dr. Metchnikoff (Paris) spoke and agreed with the views entertained by Klemperer. The increased healing or curing force of the organism is produced by the immune-rendering therapeutics, and shows itself by the increased production of the white blood-cells, which are really the nest-destroyers of the bacteria.

Another important subject under discussion was the question of "Cirrhosis of the Liver." Prominent references were made by Professor Rosenstein (Leyden) and, Professor Stodelmann (Dorpat).

Professor Rosenstein gave a brief historical review of the development of the study of liver cirrhosis since the fundamental studies and examinations of Laennec and Charcot. From the latter investigator the subdivision of liver cirrhosis into contracted and hypertrophic was first sharply defined and formulated, and distinctly separated.

Among English clinicians Todd accepted and agrees with the latter formulation.

In Germany there remained, however, contrary to the opinions of the observers above mentioned, the prevalent idea, that these two conditions of the liver were merely different stages of the same disease, and that the contracted stage usually preceded that of the hypertrophic stage. He further believes that the different histological processes, and the different previously observed clinical symptoms, are the result of two entirely different diseases, the one the hypertrophic, the other the atrophic, cirrhosis of the liver; but adds that a third condition, characterized by its short duration, is also observed, wherein we first find an enlargement and then a contraction of the organ.

Professor Stadelmann does not accept the reasons for a distinct division as already mentioned, but adheres rather firmly to the old theory that we are dealing with several distinct stages of the same disease. Among the causes which especially induce the atrophic cirrhosis of the liver, alcohol is the most frequent one. Furthermore, the etiological factors must be taken into consideration—lead-poisoning and different infectious diseases, syphilis, tuberculosis, malaria. For the other forms the causes are unknown.

The reason for the most characteristic symptom causing hypertrophic cirrhosis of liver—the icterus—has not been yet sufficiently proven.

A very lively discussion bore upon certain maxims for the separation of the two forms of cirrhosis of the liver, and also their symptoms and therapeutics, and was participated in by Professors Müller, of Marburg; Fürbringer, of Berlin; Ackerman, of Halle; v. Liebermeister, of Tübingen; Ebstein, of Göttingen; Lenhartz, of Leipsic; Minkowski, of Strasburg. Professor v. Frey, of Leipsic, referred to a very interesting observation that icterus, after closure or obstruction of the ductus choledochus, would disappear when a ligature was placed around the ductus thoracicus.

The remaining papers read, numbering fifty seven, comprised all subjects pertaining to internal medicine. It would, however, carry us too far to try to outline them, but we will try to give a brief *résumé* of two of the most important of these.

One is entitled "Suggestions on Therapeutics and Hypnotism," by Professor Binswanger, of Jena, one of our most prominent psychiatrists. The supporters of hypnotism believe that it should be universally adopted by physicians. This is wrong, for the benefits are not such as to warrant its acceptance by the majority of medical practitioners. How is it, then, that these hypnotizers have such wonderful successes, and the general practitioners have not? The answer is: That the *hypnotiseur* brings large statistics, and endeavors to cure by their means. So, for example, they treat many diseases that would get well by many other known means, and then ascribe the cure to hypnotism. It is plain that those disorders dependent on the brain are those most accessible to this plan of treatment, excepting, perhaps, those functional disorders, *e.g.*, insanity.

Two important antagonistic points appear here in the treatment of the functional neuroses: 1. The management of pain; 2, insomnia.

Against severe pains these hypnotizers admit that their methods are powerless. Here the object is to attain relief from the pains, and this has been successful in one-eighth of all cases. The sleep produced by hypnotism is very quieting and refreshing, and the contrary of chloroform sleep. Doubtful is the stand-point to be taken in the treatment of hysteria, for it is frequently very difficult to hypnotize these hysterical patients, as at the time the *hypnotiseur* wishes to act the patient is frequently seized with hysterical spasms.

In all cases the successes are only temporary, the patients go back to their former condition and suffer relapses.

The brilliant results attained in the treatment of morphinismus must be carefully considered and cautiously ac-

cepted, for the hypnotic method still lacks a proper physiological basis.

It still is proper to give credit to the psychological healing methods, inasmuch as the suggestion, while the body is awake, constitutes the psycho therapeutics, cheers the patient, and makes him forget his real sufferings.

A very important discovery in the treatment of diabetes was mentioned by Professor Ebstein (Göttingen). He recommends a new nourishing substance called *aleunorat.*

It has the property of a dry, floury substance, yellowish color, tasteless, and odorless. It contains about eighty to eighty-six per cent. of albumin and only seven per cent. of carbohydrates. With this aleunorat flour various substances and preparations can be made to suit the diabetic.

So, for example, it can be utilized for soup, for sauces, for vegetables, and as a bread flour. It can be prepared for a daily bread, the aleunorat bread containing fifty to sixty per cent. of albumin. The bread has no disagreeable taste, and is decidedly cheap, which is an advantage for poor people.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending June 11, 1892.

	Cases.	Deaths.
Typhus fever	2	1
Typhoid fever	4	7
Scarlet fever	120	21
Cerebro-spinal meningitis	2	6
Measles	551	54
Diphtheria	66	26
Small-pox	9	0
Varicella	0	0
Pertussis	0	0
Erysipelas	0	0
Leprosy	0	0
Mumps	0	0

A Plan for the Promotion of Temperance, not teetotalism, that would doubtless be very popular here as well, was that of the late Count von Moltke. He believed that the most reasonable and feasible plan for minimizing the injuriousness of drink was to reduce the price of sound light beer.

The Chemical Pathology of Diphtheria.—In the "Gulstonian Lectures" recently delivered at the Royal College of Physicians, London, Dr. Sidney Martin discussed the chemical pathology of diphtheria and compared it with that of anthrax, infective endocarditis, and tetanus. Speaking first of anthrax, he said that if its bacillus were grown in a medium which resembled the fluids of the body (by containing an animal proteid and a certain proportion of mineral salts), it digested the proteid with the formation of products resembling chemically those found in peptic and in tryptic digestions—with the exception that the final product was a base, an organic body forming salts with acids. The two classes of products were both found to be present in the blood and tissues of animals suffering from the natural disease, but the amount of the alkaloid was much greater than that of the albumoses, and an investigation of the physiological action of the products showed that the alkaloid was the chief agent in producing death. When introduced into the body the bacillus began to digest the proteids, the products of digestion caused a local œdema containing (like other pathological effusions) a large quantity of proteids in solution—proteids which were outside the metabolism of the body, and which, therefore, served as a suitable food for the bacillus. The absorption of the digested products from the local œdema and from the other parts of the body in which the bacillus grew, produced the symptoms of the disease, and it was to the gradual accumulation of the poisonous anthrax base that the stupor ending in coma and death was due. These bodies were the specific products of the bacillus, and were readily recognized either in a cultivation, or when separated from the tissues of an animal dead of the disease.

The chemical study of diphtheria was commenced by examining the tissues of patients dead of diphtheria, in the first instance, before making any attempt to isolate the products of the bacillus diphtheriæ. Two classes of substances were found present, but whereas the bacillus anthracis produced albumoses and an organic base, in diphtheria we had albumoses and an organic acid. The albumoses of diphtheria could not be distinguished from those of anthrax or from those of peptic digestion by chemical means, but only by their physiological effect. The intra venous inoculation of rabbits with the albumoses found in the tissues in diphtheria produced a local œdema, fever, paresis of the muscles, loss of weight, and diarrhœa. A striking feature of the action of these albumoses was that the effects might be prolonged. The blood of animals dying after injections was found to coagulate slowly. This slow coagulability of the blood (which was a well-known feature of the action of albumoses on the blood) showed that in animals dying several days after inoculation the diphtheria albumoses were still present in the blood, and this condition of the blood in animals explained why diphtheritic paralysis in man could occur some time after the acute disease was past. The organic acid found in the bodies of diphtheria patients was, like the albumoses, a nerve-poison and capable of producing the same anatomical changes in the nerves. (These changes were described at some length by the lecturer.) The chemical and physiological examination of the diphtheritic membrane showed that there existed in it a poison associated with the proteid and precipitated by alcohol, which produced exactly the same result as the albumoses found in the blood and spleen of diphtheritic patients. It was, however, a poison much more virulent, since a single dose produced a result which only multiple doses of the albumose could effect. Dr. Martin observed that it had been shown that the bacillus diphtheriæ formed from proteids products of the same chemical nature as those found in the bodies of patients dead of diphtheria, viz., albumoses and an organic acid. The albumoses formed by the bacillus diphtheriæ in artificial cultivation had in single and multiple doses the same physiological action as those found in cases of diphtheria in man. The bacillus diphtheriæ was, therefore, the primary infective agent in diphtheria. The bacillus liberated in the membrane a ferment which, when absorbed, digested the proteids of the body, forming albumoses and an organic acid. These digested products were the agents in causing death, and in producing the fever, depression, and the paralysis which followed diphtheria. It was clear that the diphtheria products found in the body did not all come direct from the membrane. The large amount of albumoses and organic acid found in the spleen showed that something more than absorption from the membrane was going on. It was probable that the ferment absorbed from the membrane digested the more or less stagnating proteids in that organ, and we knew, indeed, that the spleen contained a proportionately larger quantity than the blood of bodies formed from proteids, such as uric acid, xanthin, etc. A chemical examination of the blood and spleen in a case of endocarditis showed that the same two classes of products were present as in anthrax and diphtheria, viz., digested proteids or albumoses, and a non-proteid product which, when first separated and purified, was strongly acid. The same two classes of poisons were found to be present in tetanus.

Dr. Martin said it had become clear to him that these chemical products were specific in their action—that those formed by one bacillus were separable to a certain

extent chemically, to a greater extent physiologically, from those formed by other pathogenous micro-organisms. The rôle of the spleen was obscure, but the chief point about the organ, from a pathological point of view, was that the blood flowed through the walls of the vessels into spaces; thus we had a more or less stagnating fluid, the proteids of which could be digested either by micro organisms, or by ferments. In anthrax and infective endocarditis the organ was greatly enlarged; it was usually normal in size in diphtheria. In all three cases it was the proteids of the spleen from which the specific poisonous products were mainly formed; they served as the food of the infective agents, primary or secondary. Pathological effusions, whether already present in the body, or formed by the primary infective agent, were also suitable culture media; they might, speaking generally, be considered as slightly alkaline solutions of proteids which were outside the active metabolism of the blood, *i.e.*, the proteids were not in a living fluid like the blood. In diphtheria and in infective endocarditis fibrin served as the medium in which the micro-organism flourished.

In these disorders the primary infective agent or living contagium produced its effect in man by means of its specific chemical products, which it formed from the body proteids with or without the intervention of a ferment. It might be that in all cases the chemical substances were produced by means of an unorganized ferment excreted by the primary infective agent, but in only one of the diseases examined, viz., diphtheria, was there any evidence that this ferment played a direct pathological rôle. In this disease the bacillus was limited to the superficial parts of the membrane, and did not diffuse itself throughout the body. Something was excreted by the bacillus and absorbed into the body, in the tissues of which were digested products. This excretion of the bacillus was looked upon as a ferment, and was called the "secondary infective agent." In anthrax and infective endocarditis, on the other hand, the primary infective agent was in the body itself, and there was no evidence that a ferment played any direct part in the causation of the symptoms of the disease. He suspected that in tetanus—which resembled diphtheria in the fact that the primary infective agent was limited to the site of inoculation—a ferment or excretion of the bacillus acted as a secondary infective agent. The secondary infective agent could not be expressed in any chemical terms, but only in terms of what it could accomplish, either, 1, of its physiological action, or, 2, of its capacity for forming from proteids chemical bodies which resembled it in physiological action.

A Proposed Remedy for the Dispensary Abuse.—Dr. W. E. Dawson, writing to the *Hospital Gazette*, suggests that at every dispensary and hospital a register be kept, easily accessible to local medical men, giving the names and addresses of all patients attended during a given week. "Medical men would thus become so many unpaid inquiry officers of the institution; and the secretary could then always reply to complaints of abuse—why don't you prevent it by inspecting the register and giving me confidential information?"

Cause of the Death of the Duke of Clarence.—Referring to comments on the absence of a specific knowledge of the direct cause of the death of the Duke of Clarence, it is pointed out that no single member of the royal family, or indeed other distinguished personage at all, went down to Sandringham between the death and the funeral of the prince. The Duke of Edinburgh travelled up to London *en route* for the Prince of Wales's Norfolk residence, on the day of the death, but was detained in town by a telegraphic despatch requesting him not to come. Similar deterrent causes prevented the presence of other royal relatives. The utmost caution was observed until the duke's body had been embalmed and removed to the village church at Sandringham. There is nothing sufficiently serious about influenza contagion to warrant such precautions, and it is suggested that a malady much more serious, and by no means unfortunately uncommon in the royal family, supervened on the influenza symptoms in the Duke of Clarence's case. Both Dr. Broadbent and Dr. Laking have now had their audiences with the Queen at Osborne, and the *Court Circular* goes out of its way to mention them both as "prolonged." Meanwhile the Prince of Wales and his family go straight back alone to Sandringham, seeing no one.—*Provincial Medical Journal.*

A Novel Excuse for Resignation.—A lieutenant in the United States Cavalry Service has written from New York to the Secretary of War, asking that his resignation be accepted for the reason that he finds himself unable to restrain his inclinations toward insanity.

The Bill to Regulate the Practice of Medicine in Maryland has become a law. This law practically confirms the Medical and Chirurgical Faculty of Maryland in its ancient authority as a licensing body. Not in its original extent—for all practitioners; but in a limited degree—for all future practitioners except Homœopaths. The promoters of the bill deserve the thanks of the medical profession of the State and of the whole country.—*Maryland Medical Journal.*

Comparative Action of the Different Brands of Chloroform.—Professor M. Charteris and Dr. W. MacLennan have tested the action of six different brands of chloroform upon guinea-pigs, and have found the following average results:

	Anæsthesia.	Respiration ceased.	Recovery.	Remarks.
	M. S.	M. S.	M. S.	
1..	4 20.0	1 36.6	7 40	No tremors.
2..	4 21.6	1 13.33	8 50	No tremors.
3..	5 8.0	1 50.0	12 36	Rhythmic tremors distinct.
4..	4 57.0	1 26.0	11 48	Rhythmic tremors distinct.
5..	3 59.3	4 43.3	18 20	Rhythmic tremors pronounced.
6..	3 55.0	2 0.0	13 20	Rhythmic tremors pronounced.

The conclusions from this research, so far as it goes, show that there is a very evident difference of action exhibited by chloroforms of different manufacture.

Primary Cutaneous Tuberculosis by Direct Inoculation.—An instance of inoculation upon the fingers from washing the handkerchiefs containing sputa of a phthisical patient is recorded by Dubreuilh and Anché. Secondary lesions of the axillary glands and region of the shoulder took place, but after thorough scraping healing took place. Microscopical and bacteriological examination confirmed the diagnosis.—*Centralb. für klin. Med.*, No. 32, 1891.

Russian Students of Medicine.—The total number of students in the University of Moscow on January 1, 1892, was 3,396, of whom 1,096 belonged to the medical faculty. The degree of Doctor of Medicine was conferred on but twelve candidates in 1891. At Charkow the number of students was 1,010. The number of licenses to practise medicine granted last year was 112. The number of students at Kieff was 2,110, of whom 942 belonged to the medical faculty. Seventy-eight licenses to practise medicine were granted during 1891.

Is This the Medicine of the Future?—Dr. Constantin Paul, of Paris, has been treating paralyzed patients by subcutaneous injections of a solution of the gray matter of the sheep's brain. This is, of course, a development of Brown-Séquard's experiments with testicular juice as a restorer of virile strength. A physician in this country has been using injections of double distilled extract of gonorrhœal pus in the treatment of rickety children whose fathers confessed to having had gonorrhœa in their youth. This is a fact. Then there is Koch's tuberculin. What are we coming to, any way?

A STUDY OF TYPHUS FEVER,[1]

CLINICAL, PATHOLOGICAL, AND BACTERIOLOGICAL.

BY JOHN WINTERS BRANNAN, M.D.,

ASSISTANT PATHOLOGIST TO ST. FRANCIS HOSPITAL, NEW YORK;

AND

TIMOTHY MATLACK CHEESMAN, M.D.,

ASSISTANT IN BACTERIOLOGY, COLLEGE OF PHYSICIANS AND SURGEONS, COLUMBIA COLLEGE, NEW YORK.

TYPHUS FEVER is, fortunately, a rare disease in this country, and the few epidemics of which we have record are all directly traceable to importation from Europe. The reports of Dr. R. Robertson, a surgeon in the English navy during the War of the Revolution, show that in 1776 the fever prevailed among the British and American sailors in the naval hospitals at New York and Newport, but it apparently never spread to the townspeople nor to the armies operating on shore. Nathan Smith, writing in 1824, states that he saw "typhous" fever as early as 1787, in New Hampshire; but it is evident from his description that it was typhoid fever, and not typhus fever as now recognized.

The first well-authenticated outbreak of the disease was in the year 1807, at Hartford, and two or three other points in New England. The fever was epidemic in Philadelphia in 1812, and again in 1836. In was in the latter year that Gerhard made the observations which have had a large share in establishing a correct idea of the disease. The first considerable epidemic in New York was in 1847, following the Irish famine of that year. In 1861 the disease was again introduced here by Irish immigrants, and did not finally disappear until three years had elapsed. Since that time it has been twice mildly epidemic in this city—in 1881, and again in February of the present year. In all these cases the fever was brought to this country by immigrants from regions where it is endemic. It is an interesting fact that the disease has never become endemic here, but has always disappeared when suitable hygienic measures have been brought to bear upon it. It is believed to be always present in Ireland, Russia, Poland, and Bohemia. This endemicity has been attributed to certain characteristics of the races in those countries, which serve to perpetuate the germ. But we have many thousands of those races here, and yet the disease never breaks out among them spontaneously, nor do they show an especial susceptibility to the imported contagion. In the recent epidemic, indeed. the mortality was much heavier among the Americans who acquired the disease than among the Russian Hebrews who brought it with them. The fact that typhus fever was not introduced into America until comparatively recent years has probably much to do with our exemption from its ravages. Had the immigrants of the last century been infected with the disease, it might well have obtained a firm foothold among us. But modern sanitation has taught us how to fight such diseases, and it now requires but a comparatively short time to get them under control, provided they are recognized before they have spread too widely.

A comparison between the epidemic of 1861 and that of February of this year will show what can be accomplished by intelligent and energetic hygienic measures. In 1861 [1] the first case was that of a little girl, who was brought into a tenement-house in Mulberry Street, ten days before she became ill, from a ship which had had cases of typhus fever on board. Two weeks after her illness began, her aunt took the disease and died. In gradual succession nearly every family in the building took the fever. Becoming frightened, some of these families moved into other streets, formed the nucleus for the development of the disease in different localities, and it soon became a widespread epidemic. There was constant and unrestrained intercourse between the healthy and the sick. As a result of this lack of supervision and control the epidemic lasted for three years, and several thousand persons suffered from the fever. Let us contrast these figures with those of the recent epidemic

On February 11th, Dr. Edson, Chief Inspector of Contagious Diseases, learned of the presence of 44 cases of typhus fever in this city. All these cases were among Russian Hebrews who had arrived in this port a few days previously in the steamship Massilia. This emergency called for immediate action. As stated by Dr. Edson,[2] there are only two ways of fighting typhus fever. These are: 1, Isolation of the sick and those exposed to the contagion; and 2, the destruction, or thorough disinfection, of all articles which may have come in contact with the sufferers. These measures were both carried out on this occasion, with the result that the disease was soon well under control. The sick persons, as well as all known to have been exposed to the contagion, were at once transferred to the Hospital for Contagious Diseases on North Brother Island. The 44 original cases had been found distributed in several lodging-houses filled with other Hebrews, and yet only 185 persons in all suffered from the fever.[3]

It is now generally admitted that typhus fever never arises spontaneously, but is always due to contagion from a previously infected individual. But there are certain conditions which favor greatly the spread of the specific poison. These conditions are overcrowding, filth, and destitution. Murchison, indeed, believed that such conditions of themselves were sufficient to generate the disease *ae novo*. David Hosack, also, as a result of his observation of the disease in New York, wrote, in 1820: "Typhus is the product of confined human effluvia, the result of the filthy mode of living unavoidable among the poor." Such was the common opinion in the early part of this century among physicians both in Europe and in this country. Murchison cites many observations in support of his theory of spontaneous generation, but in the light of modern experience they carry no weight whatever.

The importance of early diagnosis has been alluded to above. Unfortunately, during the first two or three days

[1] The clinical observations recorded in this paper were made in the wards of the Riverside Hospital, on North Brother Island, New York City.

The writers desire to express their thanks to Dr. Cyrus Edson, now Sanitary Superintendent of New York City, to whom they are indebted for the privilege of visiting the Riverside Hospital; and to Dr. F. R. Percival, late Resident Physician at the Hospital, who gave them most efficient aid in the wards of that institution.

To Professor T. Mitchell Prudden, Director of the Pathological Laboratory, College of Physicians and Surgeons, Columbia College, they wish to express their obligations for his advice and assistance, rendered during the pursuance of their histological and bacteriological researches in the laboratory.

[1] A. L. Loomis: Practical Medicine, p. 714.

[2] North American Review, April, 1892.

[3] Since the preparation of this paper a few additional cases have been reported.

there is but little to distinguish typhus from any other fever.

The onset is usually sudden. The patient has a distinct chill or sense of chilliness. This is followed by severe headache, and pains and aching in the back and limbs. A sense of extreme prostration is felt almost at once, and many patients take to their beds on the first day of their illness. This prostration is accompanied with loss of appetite, coated tongue and high fever. These symptoms are present within the first twenty-four hours, but are not of themselves sufficient to warrant a diagnosis of typhus fever. Perhaps at this early period the abrupt rise of temperature, reaching sometimes 40.5° C. on the first day, and the great prostration, are the most noteworthy symptoms. The prostration increases as the disease advances, reaching its maximum on the tenth to the twelfth day. The fever presents no marked remissions during the first ten days, varying but little from 40.5° C. Then it defervesces more or less rapidly in cases ending in recovery, reaching normal figures on about the fourteenth day.

The typhus facies is usually referred to as characteristic of the disease, and it was very marked in most of the cases seen in the recent epidemic. On entering a ward containing perhaps twenty five beds, one was at once struck by the uniformity of expression of the occupants. This was probably partly due to the fact that they all belonged to the same race of peculiar people, at least in the beginning of the epidemic. But the same physiog nomy was also noticeable when other nationalities were gradually introduced, taking the beds vacated by the Hebrews who had gone before. There was the same congested, dusky face. The conjunctivæ were injected, the eyelids and lips, as a rule, half opened when the patient was lying undisturbed. The absence of any anxiety in the face was also marked. Not one of the patients with whom I came in contact expressed any concern as to the outcome of his own illness, though when convalescent he was always anxious as to the condition of his relatives or friends about him.

The typhus odor, usually likened to that of mice, was not pronounced in these cases This may have been due to the bathing and constant care given to the patients by Dr. Percival, as well as to the very efficient system of ventilation insisted on in all the wards. On only one visit, when some new patients had just been brought into the ward, was the odor recognized. It was, as described, very offensive and sickening in character. All the nurses and orderlies, who of course see the typhus patients before they are washed, insist that the odor is always present and is very characteristic, especially on the first three days of the disease. If this is the case, it is a valuable symptom at a time when the fever is most difficult to recognize.

The cardinal symptom of typhus fever is, of course, the eruption. Until this appears, the diagnosis must remain uncertain. When it is abundant and well marked, especially if petechial in character, there is generally no further room for doubt. An eruption of some sort was present in all of the cases under observation on North Brother Island, but it was not very characteristic as a rule. It was usually dark-colored, but often very faint, the spots disappearing on pressure. In fact, many of these cases, if seen singly in their own houses, and without a history of exposure to contagion, would probably go unrecognized Petechiæ were very rare, but present and persistent after death in most of the fatal cases.

Many of the above symptoms are to be noted only when the disease has been under observation for a certain length of time. Even when the principal ones are present, including the eruption, the diagnosis must sometimes be doubtful in the absence of a history. Dr. A. R. Mott[1] cites a case in illustration of this: A man was brought into Bellevue Hospital from the street, unconscious, and supposed to be drunk. The surface of the body was of a dusky hue, the face flushed, the eyes injected, and the pupils small. Over the abdomen and chest, and upper parts of the arms and thighs, were scattered, rather profusely, small petechial spots, mostly of minute size. The temperature was 40° C., the pulse 120, the respiration 36. Dr. E. G. Janeway saw the patient, and, while agreeing that the case was probably one of typhus, he saw nothing in the conditions that might not be as well explained—in the absence of previous history—by the presence of acute ulcerative endocarditis. The patient lived for thirty-six hours, and died without recovering consciousness. On autopsy, well marked ulcerative endocarditis was found, with embolism of the middle cerebral and other smaller arteries of the brain, and infarcts in various organs. The spleen was normal in size and consistency.

[1] American Journal of the Medical Sciences, April, 1884.

There are other diseases, more common than ulcerative endocarditis, which may closely simulate typhus fever in many, if not all, of its symptoms. Such are, more especially, typhoid fever, measles, meningitis, acute lobar pneumonia, and uræmic coma. The history and course of the disease, with attention to the physical signs, are usually sufficient to enable a diagnosis to be made.

Of the one hundred and eighty-five cases on North Brother Island twenty-eight died, giving a mortality of fifteen per cent., which is rather less than the usual rate. Some of the deaths were due to complications, but the majority to the fever itself. Four autopsies were made, and all the organs examined except the brain and spinal cord. The pathological appearances were pretty nearly the same in all, varying only in degree. These lesions were—acute degeneration in the liver and kidney, with swelling and hyperplasia of the spleen. The other viscera presented no noteworthy changes.

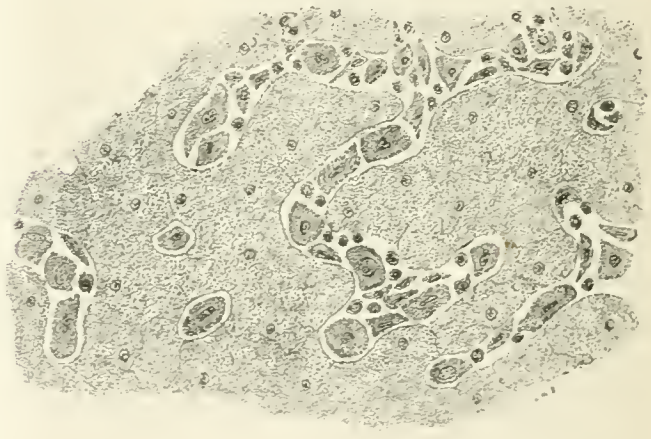

Fig. 1.—Section of Liver, showing Cells in the Capillaries.

In the liver there was a moderate degree of swelling and increased granulation of the liver-cells. Careful search was made for such minute foci of cell-necrosis as have recently been described as present in several acute infectious diseases, but with negative result. In one case, which died while the temperature was very high, I noticed, in a degree which is very unusual, an accumulation of large, irregular, moderately granular cells, either free in the liver capillaries or clinging to their walls. These cells appeared to be swollen and detached endothelium. A typical portion of this liver is represented in Fig. 1. I would not attach especial significance to this lesion of the capillaries in connection with this disease, but simply record it as a contribution to the too little understood lesions of vascular endothelium in acute infectious diseases.

The kidneys showed granular degeneration of the tubular epithelium, with considerable disintegration. The spleen presented the usual appearances of acute hyperplasia.

J. W. B.

The most important studies hitherto made on the etiology of typhus fever are those of Hlava, of Thoinot and Calmette, and of Lewaschew.

Studies of Hlava.[1]—In 1888 Hlava, during an epidemic of typhus fever in Prague, examined bacteriologically the blood and viscera of thirty-three cadavers, and the blood-crusts and urine of ten cases during life. A bacillus was isolated from the blood of twenty of the cases which had died, and from two of the living patients. This bacillus differed from any known form. He described it as an "ovoid coccus," or a very short bacillus, growing in pairs and in chains. From this latter growth-character he termed it a "strepto-bacillus." Its diameter varied from 0.9 μ to 1.2 μ, the length of the ovoids was about 0.9 μ, that of the bacilli 1.8 μ, while the terminal individuals of the chains grew to the length of 2 to 3 μ. In broth it developed rapidly at body temperature, forming chains, and was without visible spores. No growth was obtained in gelatine at 20° C.

Plated in agar, the deep colonies were circular or oval, and opaque, the surface colonies circular, lace-like, and whitish, with an opaque centre and transparent edges. The diameter of the largest colonies did not exceed 2 mm., and when magnified about one hundred diameters they appeared granular and showed very fine threads on their borders. The growth on human blood-serum presented the same characters. No growth was found on potato. Human and veal broth showed a rapid growth, which settled in the form of a white precipitate, while the fluid above remained clear. The "strepto-bacilli" died in eight days in broth, and in twelve to fourteen days in agar. They stained with all the aniline dyes and by Gram's method.

Culture inoculations of the strepto-bacillus in rabbits, guinea pigs, dogs, cats, mice, and pigeons were not fatal; a slight elevation of temperature was noted for a few days, after which they recovered. The animals were killed and platings made from the organs, but the inoculated bacillus was not found.

Inoculations in two young pigs gave more positive symptoms. In one case the temperature rose to 41.4° C. on the eighth day, and for sixteen days remained above 39° C. On the fifth day small reddish spots appeared on the skin, and disappeared after three days. In the other case no spots appeared.

Loss of appetite and flesh were marked symptoms in both cases. The animals were killed, and on autopsy showed a "degeneration" of the kidneys and tumefaction of the spleen. The bacilli were not found in the blood or spleen, but were found in the kidneys of one case, and in an area of broncho-pneumonia in the injected lung of the other. Virulence of the cultures for young pigs was lost after a short time.

Thus, in brief, Hlava found the "strepto bacillus" in the cadavers of twenty out of thirty-three cases which had died of typhus fever, and in two out of ten cases, from the blood during life. The results of his animal experiments seem to be of little significance.

Studies of Thoinot and Calmette.[2]—These writers studied seven cases of typhus fever during an epidemic of the disease on the island of Tudy. Platings were made from the blood of all the cases and gave negative results. Inoculations of blood were made in rabbits, guinea-pigs, and pigeons, with negative results. The only positive results obtained were from the examination of fresh unstained blood, and in this these observers found constantly present, certain motile "granules," measuring 1 to 2 μ, provided usually with a short, thread like prolongation. Unattached motile threads were also found. These bodies moved rapidly among the blood cells. The writers claim that this "organism" differs from forms of degenerated blood-cells described by various writers.

[1] Hlava: Archives Bohême de Médecine, 1889-90, vol. iii., p. 122 (Sborink Lékârský).

[2] Annales de l'Institut Pasteur, tome vi., No. 1, January, 1892.

Studies of Lewaschew.[1]—Lewaschew found constantly in fresh blood from the spleen in "numerous cases"—he does not state how many—minute organisms, sometimes appearing as threads, sometimes as spheres having a thread-like attachment, which move actively among the blood-cells. He also obtained from spleen puncture and finger-blood a slow-growing micrococcus which he has not yet described, nor does he state the number of cases in which he found it.

Original Studies.—The primary purpose of this paper is to record the results of a morphological and biological study, made during the recent outbreak of typhus fever in New York City, with a view of throwing some light, if possible, on the etiology of the disease.

The material was furnished to me by Dr. Brannan, and consisted of the viscera from three cadavers, and blood obtained by finger-puncture from six living patients during the height of the disease, while the temperature recorded was 40° C. or over.

Examination of the Viscera.—These were brought to the laboratory uncut, wrapped in cloths moistened in one pro mille bichloride solution, and platings and sowings were made at once on their arrival, with the usual precautions against contamination. Portions were hardened in alcohol for morphological study.

Case I.—Sections[2] of the spleen and kidney were stained by Gram's method, and examined under a one-sixteenth oil immersion, for any micro organism which might be present, but none were found.

Platings were made on six per cent. glycerine, agar, and sowings in beef broth, from the heart's-blood, spleen, and kidney, and kept at 37.5° C. and at room temperature. The plates were kept under observation for twelve days, and the tubes for a much longer period, but no growth occurred.

Case II.—Sections of the spleen and kidney were stained and examined as in the former case, with a like negative result.

Cultures were made as in Case I., but only a negative result was obtained after twelve days of observation.

Case III.—In sections of the spleen, liver, and kidney no micro-organisms of any kind were found.

Cultures were made from the heart's-blood, spleen, kidney, and liver. The platings were on beef blood-serum, and on six per cent. glycerine agar, in Petri dishes, and in Blücher's anaerobic plates. The sowings were in beef blood-serum, both fluid and coagulated, in sealed and unsealed tubes; in beef broth and glycerine agar tubes; by deep puncture in alkaline agar tubes, and in Nikiforoff's anaerobic tubes, charged with six per cent. glycerine beef broth. All of these cultures were kept at 37.5° C., and were studied daily for sixteen days, many of the tubes for a much longer period. In no case was there any growth, except some scattering later contaminations on the plates.

Examinations of the Blood.—The blood, obtained under strict antiseptic precautions from the six living patients, was streaked on six per cent glycerine agar plates, and smeared on sterilized cover-glasses by Dr. Brannan, and brought at once to the laboratory. The cover-glass blood-smears from all the cases being dried at once in the air, were fixed in alcohol, and stained in Czenzynski's solution for eighteen hours, at room temperature. Although all of these covers were examined throughout with a one-sixteenth homogeneous immersion lens in the most careful manner, in only about one-half of them a few blue-stained bacilli were found, never more than eight or ten on a cover. In length they never exceeded one third of the diameter of a red blood cell, although usually not more than half that length. The diameter was not more than half the length of the smaller bacilli. They were round-ended, and were usually found singly, lying apart from the blood-

[1] Deutsche Med. Wochenschr., Bd. 18, No. 13, p. 279, 1892.

[2] These sections were examined by me only for micro-organisms; the histological examinations are described above by Dr. Brannan.

cells, but in a few instances groups of from three to six bacilli were seen

Platings, made from the blood of the six patients, were kept at 37.5° C., and showed a growth of colonies among the blood-cells in from two to four days. In all of the cases some of the plates remained sterile, while the plates on which growth was found developed a very variable number of colonies. In one case between sixty and seventy colonies developed on one plate, in another case twenty-six were found, while but one single colony was developed on each of two plates in one of the cases examined. These colonies, while thus present in varying numbers in all of the six cases, presented the same general appearance. Cover-glass preparations showed that the colonies were formed of small bacilli, and subsequent morphological and biological study has proved them to be identical in all the different cases.

Description of the Bacillus.—*Morphology.*—The diameter of the bacillus varies from 0.5 μ to 0.8 μ, and the length from 1.0 μ to 2.5 μ. It occurs singly and in pairs (Fig. 2),

Fig. 2.—Bacilli from Culture, showing Irregularities of Form and Staining.

infrequently in short chains of six or eight. It is often club shaped, and is found to be ovoidal in young cultures. It stains readily with the ordinary aniline dyes, and retains the color after staining by Gram's method. After some days' growth certain of the bacilli stain irregularly, presenting a sort of mottled appearance. The bacilli are immobile, and spores were not found, although some of the club-shaped bacilli show circular unstained spots which do not color by the methods usually employed for spore-staining.

Mode of Growth.—Under the most favorable circumstances growth is not voluminous. The most abundant growth obtained was on beef blood-serum at 37.5° C. No growth was obtained on gelatine, nor on any medium at a temperature under 27°. C. Development occurs under mica plate, and in an atmosphere of hydrogen, butthe growth is not so abundant as in aerobic cultures.

The colonies of this bacillus growing on six per cent. glycerine agar plates present to the naked eye, in about eighteen hours, in oblique light, a scanty growth, consisting of minute, bluish gray, translucent spots. The diameter of the largest colonies at this time does not exceed 0.25 mm. Older colonies appear dry and scaly to the naked eye, are flat, whiter, and more opaque, and never exceed 2 mm. in diameter. These colonies, when examined by a hand magnifying-glass, show a central thickening. The younger colonies, examined under low powers, are rounded in outline, the surface is granular, the edge sinuous and sharply defined. On very moist agar the sharp definition of the edge is lost. Under these low powers the colony has a pale brown color, which is deeper in the centre and in scattered points over the surface, an appearance probably due to the irregular heaping of the growth. When magnified about one hundred diameters the surface appears coarsely granular, and the edge is formed of short, coarse, irregular spiculæ.

Glycerine agar tubes at 37.5° C. show the same surface-growth appearances as the plates. In the line of puncture small, white, isolated colonies occur, and in the condensation water there is a white deposit, quite perceptible in twenty-four hours, the fluid above remaining clear.

On coagulated beef blood-serum, at 37.5° C., the growth is slightly elevated, white, and shiny. In beef broth at 37.5° C. the growth is slight, and settles in the form of a white precipitate, the fluid above remaining clear. In milk at 37.5° C. growth occurs in the form of a white deposit—the milk undergoes no apparent change. No visible growth was obtained on potato or on macaroni.

Animal Experiments.—Inoculations of from $\frac{1}{4}$ to $\frac{1}{2}$ c.c. of a broth culture from patient J. S—— were made in the ear-vein of two rabbits, and in the subcutaneous tissue of the abdomen of one rabbit and two guinea pigs, and in two white mice.

All the animals lost flesh rapidly. The two guinea-pigs died on the tenth day, on the twelfth day one mouse and one rabbit died, and on the thirteenth day the remaining mouse died, and the two remaining rabbits were killed. Examinations of all these animals, made as early as practicable after death, showed nothing abnormal in the gross appearance of the viscera. Cultures were made from the blood and viscera of the guinea-pigs, and from the heart's-blood of all the other animals, but the inoculated bacillus was found only in the case of the rabbit which died on the twelfth day after inoculation in the ear vein.

Another series of inoculations were then made in the ear-vein of five rabbits, of about $\frac{1}{3}$ c.c. each, of a seven-day broth culture from patient M——. The animals all showed marked emaciation, and all of them died, one each on the nineteenth, twenty-first, twenty-third, twenty-fourth, and twenty-ninth days. The heart's-blood of these animals was plated, and the inoculated bacillus recovered only from one set of plates, those made from the rabbit that died on the twenty-first day.

Summary of Inoculation Experiments.—Inoculations of cultures of the bacillus obtained from two of the cases were made in eight rabbits, two guinea pigs, and two white mice. All the animals showed marked emaciation, and with the exception of two rabbits all the animals experimented upon died in from ten to twenty-nine days. The inoculated bacillus was recovered from the heart's-blood of two of the rabbits that died.

Remarks.—The bacillus found seems to be a species hitherto undescribed. Biologically it bears considerable resemblance to the "strepto-bacillus" of Hlava—morphologically it differs, being somewhat smaller and there being but the slightest tendency to the formation of chains, which in the case of the bacillus of Hlava is described as a marked character. A striking difference is also shown in the effect of its inoculation in animals.

All things considered, the writer cannot believe this bacillus—for which the name Bacillus Sanguinis Typhi is suggested—to be identical with the "strepto-bacillus" described by Hlava.

General Summary.—Morphological and biological examination of the blood and viscera of three patients, dead of typhus fever, gave a negative result.

Morphological and biological examination of finger-blood from six living patients showed in every case the presence of a bacillus in very small numbers. This bacillus is pathogenic for rabbits, guinea-pigs, and white mice, but though pathogenic in these animals the effect which it produces upon them is not one contributing material evidence in favor of its etiological relationship to typhus fever. Indeed this is what might be expected, since, so far as we know, these animals are not subject to the disease. The fact of finding a new species of bacillus in the blood of six consecutive patients, with uncomplicated typhus fever, in the height of the disease, seems significant, and is suggestive of an etiological relationship of the bacillus found to the disease.

This relationship cannot be determined by a single limited research. The proof must be furnished by an accumulation of evidence, either along lines such as have been pursued in this investigation, or in directions which may present themselves as our knowledge increases.

T. M. C.

LATIN AND GREEK FOR STUDENTS WHO CANNOT PURSUE A COLLEGIATE COURSE.[1]

By E. L. HOLMES, M.D.,

CHICAGO, ILL.

INCOMPLETE is a discussion of this subject (preliminary education) that does not include a consideration of the great value of an elementary knowledge of Latin and Greek.

I disclaim any attempt to prove that devotion to these languages for the purpose of reading their literature is requisite or even desirable as a preparation for the study of medicine. The field of modern literature and of modern science has become so vast and important that the average student will find neither time nor relative profit in the endeavor to master the ancient classics.

I do, however, earnestly advocate the study of the rudiments—I mean simply the rudiments of Latin and Greek—as the most valuable labor-saving instrument in acquiring an English, a scientific, and a medical education.

I ask indulgence, if I dwell somewhat at length on this portion of my subject, for I think we are in danger of losing sight of the many and great benefits which every true student will receive from a judicious study of some things in these living dead languages.

Consider for a moment the vast array of technical terms and of common English words in our general and our scientific literature, which are almost pure Latin and Greek words. . . .

Look at this remarkable series of paradoxes! A young man may never have learned a single word of Latin or Greek, and yet under ordinary circumstances he has learned, by hearing and reading English, several hundred Latin and Greek words; if he is especially intelligent, at least three thousand of them. When he receives his degree of Doctor of Medicine, he has learned by the most painful toil several hundred technical terms taken from these languages, and still does not know a single word of Latin or Greek.

He can count in Latin and Greek, and yet is in blissful ignorance of his knowledge, for he could not give on demand a single numeral of these languages. He already knows the names of several colors, of several of the elements, and yet cannot tell one of them. He knows the Latin and Greek names of every member of the body, of every organ, tissue, fibre, and fluid, and of all their diseases, of all the senses and functions, and the words to express measuring, writing, and describing. If he were asked to give the Latin and Greek synonyms for any one of them, he could not give it.

The medical student who enters upon the study of his profession in total ignorance of Latin and Greek expends a large portion of his time and energies in painful and almost fruitless attempts to acquire a knowledge of technical terms. It is doubtful whether the average student of this class ever in his life clearly comprehends our best medical literature.

The Latin Grammar which I would propose, should contain scarcely more than forty pages of declensions and conjugations, with only a very few rules. The Reader should comprise at least a hundred and fifty pages of pure, even elegant, Latin from classic prose and from poetry. Both the Grammar and the Reader, save perhaps fifty connections and other important words, should contain no words which are not good English words, with possibly a slight change of letters or syllables.

We will present a few examples:

. "Labor omnia vincit;" "Poeta nascitur non fit;" "Homo sum, humani nihil a me alienum puto;" "Pallida mors æquo pulsat pede pauperum taburnas regumque turres."

"Facilis descensus Averno:
Noctes atque dies patit atri Janua Ditis.
Sed revocare gradum superasque evadere ad auras,
Hoc opus, Hic labor est."

[1] From a recent doctorate address in Rush Medical College, Chicago.

Literæ "adulescentiam alunt, senectutem oblectant, secundas res ornant, adversis perfugium ac solatium præbent, delectant domi, non impediunt foris, pernoctant nobiscum, peregrinantur, rusticantur."

As the multiplication-table must be committed to memory before the child can progress in arithmetic, so the few pages of declensions and conjugations must be memorized carefully, that the beginner may become perfectly familiar with Latin terminations. With this preliminary exercise the scholar will find no perplexities, and will easily read the sentences in the reader.

In the vocabulary at the end of the Reader, every principal word should have all the cognate words arranged alphabetically with it. With the definition of each Latin word should be presented all English words derived from it.

I would lay stress on the value of memorizing, by easy tasks, the classic sentences I have just described.

The same plan should be pursued in teaching the elements of Greek. Thirty pages of grammar, each word of which, with a few exceptions, should be an English word, would suffice.

There would be some difficulty in filling a Greek Reader with gems of Greek literature which would also be English. A competent Greek scholar, however, with the aid of fifty connectives and other important words not English, could compile a few such sentences and paraphrase others. He could arrange a simple narrative of facts from history, geography, biography, and mythology, in which the several hundred Greek words in our language could be formed into quite long sentences and convey much useful knowledge.

Pardon me for reading a dry list of familiar syllables to call to your minds a multitude of Greek-English words, which properly arranged, would fill many pages of instructive reading—gram, graph, logue, meter, asm, scope, sis; words commencing with a or an, dia, kata, para, apo, hypo, hyper, hydro, phos, sym or syn, phil, peri, tech, tel; and words in which the following are important syllables: hepat, soma, stoma, ptoma, tomy, pneuma, deme, crat, arch, bion, phon, tone, and sark.

There is great need of such elementary text-books for the use of professional students, the preparation of which is worthy of the attention of any ingenious and thorough Greek scholar. As far as I know, those which have heretofore been compiled are not provided with vocabularies sufficient for the use of students. The space devoted to grammatical forms is also inadequate. Moreover the quotations and other sentences in the readers are not selected on account of beauty of thought and elegance of expression as suitable for memorizing. Furthermore, they do not seem to be selected for the useful information they convey.

The above method presents a short course in the study of Latin and Greek which is exceedingly easy. It utilizes the material already in the possession of the pupil and does not lead him into a bewildering, almost limitless, field of a totally unknown vocabulary and of strange idioms. It is suited to the needs of all students of these languages. Those who will prepare for college can finish this course and pass to a higher. Those who will devote but one or two years to this study can easily master the fundamental principles of the grammar and of construction, and acquire a far greater practical knowledge of Latin, Greek, and even English, than in a much longer time by the methods usually pursued in our high-schools.

Finally, this plan will not conflict with any "method" which a teacher may pursue.

After this study of English Latin and Greek, the student can understand without difficulty the technical terms of every science in every modern language. He is also able to trace the derivation and meaning of new terms which constantly appear in every department of science. He possesses the key by which he can acquire two modern languages in the time otherwise required for one. He enjoys a deeper insight into the spirit of all literature.

He has a systematic knowledge of sufficient Latin and Greek to enable him to continue alone the reading of the classics, if he has the time and taste so to do. He has increased and perfected the vocabulary of his own language, which in very great degree is a measure of mental development and which possesses an intrinsic value almost beyond estimation.

Therapeutic Hints.

Treatment of Lupus Erythematosus of the Eyelids and Face.—Brocq (*British Journal of Dermatology*, 1891) recommends in this disease:

℞. Salicylic acid..... ʒ ss.
Lactic acid..... ʒ ss.
Resorcin..... gr. xlv.
Zinc oxide..... ʒ ij.
Vaselin..... ʒ xvij.

The following is also usually well borne:

℞. Salicylic acid..... 1 part.
Pyrogallol..... 2 parts.
Vaselin..... 20 parts.

This is to be rubbed in at night. During the day the first named may be applied, the two being thus used conjointly.

Gastralgia in the Gouty. — Dr. Dujardin-Beaumetz has had good success in relieving the gastric pain associated with the uric acid diathesis by means of chloroform water given according to the following formula:

℞. Chloroform water..... ℥ ij.
Syrup of orange..... ℥ j.
Simple syrup..... ʒ j.

Sig.: A dessertspoonful every fifteen minutes until the pain is relieved.

Butyl-Chloral for Facial Neuralgia.—Butyl-chloral has been proved to have an especial action on the facial or trigeminal nerve. Given internally in doses of from one to three grains, it has a marked effect in relieving painful neuralgias of this nerve. Professor Liebreich, of Berlin, prescribes it as follows:

℞. Butyl-chloral..... gr. xl. to lxxv.
Alcohol. rect..... f ʒ ijss.
Glycerini..... f ʒ v.
Aquæ dest.....q. s. ad f ℥ iv.

Misce. Signa: From two to four teaspoonfuls p. r. n.

—*The Physician and Surgeon.*

Injections for Chronic Cystitis. — Ultzmann recommends the following prescriptions in the treatment of this troublesome condition:

Crystallized carbolic acid..... gr. xv.
Distilled water..... ℥ iijss.

Dissolve, and mix with equal parts of hot water at the moment that the liquid is to be injected.

Or the following:

Boric acid..... ℥ ss.
Glycerin..... ℥ j.
Distilled water..... ℥ x.

Make a solution, and mix with equal parts of warm water at the moment of employment.

—*Buffalo Medical and Surgical Journal.*

Treatment of the Malarial Cachexia.—In a case of a man twenty five years of age, with the malarial cachexia, Professor Da Costa prescribed the following:

℞. Liquor. arsenici chloridi..... ... gtt. v.
Tinct. ferri chloridi..... gtt. xx.
Elixir,
Aquæ..... .....āā q. s. ad f ʒ j.

M. To be taken three times a day, after meals.

Also, for the first four days, give quinine, gr. viij., in the morning on an empty stomach, and repeat the dose in the evening. Then continue by giving gr. viij. in the morning only; the quinine to be given in capsules or in powder.—*College and Clinical Record*

Soap in the Treatment of Affections of the Lid Margins.—Wolffberg (*Centrallblatt für Praktische Augenheilkunde*) advocates, from the hygienic standpoint, the use of a neutral fluid soap as a means of washing the borders of the lids. The ciliary margins are thus freed from the milder types of the affections to which they are subject, and are protected against severe sequelæ.

Influenza.—Dr. Devereux recommends the following in the treatment of influenza attended with mental and physical depression:

℞. Spirits of camphor,
Compound tincture of lavender..... āā ʒ ij.
Spirits of chloroform..... ʒ j.
Mucilage of tragacanth..... ℥ j.
Distilled water..... ʒ iij.

M. Sig.: Tablespoonful every four hours.

Tritopine is the name of a new alkaloid obtained from the mother liquor after the separation of morphine. It has the formula $C_{24}H_{54}N_2O_2$, and occurs in the form of prisms or scales, soluble in chloroform, but sparingly so in ether. It occurs in very small proportion in opium.

Acute Coryza.—Dr. Capitan recommends the following snuff to be used every hour for the relief of acute nasal catarrh:

Salol..... ʒ ss.
Salicylic acid..... gr. vj.
Tannin..... gr. iij.
Boric acid..... ʒ ij.

The use of this powder should not be continued for more than a few hours as it is apt to excite a slight eczematous eruption along the edges of the nostrils. The following is another formula, less active yet said to have given good results.

Powdered talc..... ..... ʒ j.
Antipyrin..... gr. xv.
Boric acid..... ʒ ss.
Salicylic acid..... gr. iv.

This may be snuffed freely, as it causes no irritation of the alæ nasi as does the preceding.—*Journal de Médecine et de Chirurgie Pratiques.*

Diuretin has been used by Hare (*Therap. Gaz.*, March, 1892) in four cases without very encouraging results. Two were of mitral disease with dropsy, one of general anasarca, and one of enlarged prostate in an old man with highly concentrated urine. Here as much as one hundred and twenty grains daily were given, and instead of causing an increase in the urine the quantity appeared rather to be decreased by the drug.

Alopecia Areata has been successfully treated by Dr. Moty (*Rev. Chir. e Terap.*, No. 10, 1891), by subcutaneous injections of corrosive sublimate, in from two to five per cent. solution, so as to surround the bald spot; five or six drops being injected at a time. It is said that the injections produce neither pain, nodules, nor other disagreeable symptoms, and are much more efficacious than other plans of treatment.

Impotence, according to Gywrkovecky, may be cured in its varied forms by hypnotic suggestion, which he has also found a very useful means of treatment in masturbation, nocturnal pollutions, etc. In three cases of sexual neurasthenia he has had complete success from suspension in the Sayre apparatus.—*Wiener Med. Presse*, No. 46, 1891.

Hepatic Colic with vomiting is treated by Lemoine with a teaspoonful of the following every fifteen minutes:

℞. Chloroform,
Tinct. myrrh.....āā ♏ xv.
Mucil. acac..... f ʒ ij.
Syrupi..... f ℥ iijss.

Prophylaxis of Diphtheria is best secured for those about the patient by disinfection of the mouth, pharynx, and nose. Dr. D'Espine thinks one of the best disinfect-

ants for this purpose consists in repeated irrigation with a solution of salicylic acid, two to a thousand. This belief is founded on experiments as to the bactericidal properties of salicylic acid in this disease. It has the advantage of being harmless.

Progress of Medical Science.

Aneurism of the Carotid.—Dr. Karewski (*Berlin. klin. Wochen.*, No. 37, 1891), writing upon the diagnosis and therapy of spontaneous aneurism of the common carotid, relates the case of a man of thirty who had had syphilis seven years before. A tumor suddenly appeared on the right side of the neck, attended with pain, difficulty in swallowing and in speech. A soft tumor was made out, compressible, not pulsating, free from souffle and thrill, extending between the hyoid bone and the sterno mastoid on one side, and the supraclavicular fossa and the mastoid apophysis on the other. Exploratory puncture gave issue to discolored blood. The diagnosis rested between aneurism and hematic cyst. The tumor was cut down upon, the primitive carotid denuded and ligatured as well as the internal and external carotids, and the sac resected. There was no paralysis or cerebral anæmia, and the patient was well in fifteen days. The author insists on the diagnostic value of the compressibility of the tumor, which permits one to avoid confounding it with abscess. Treatment should consist in extirpation of the sac, the more so since with antisepsis the mortality has fallen to twenty per cent.

Toxic Symptoms after Ichthyol.—Dr. Bergerio (*Gaz. d. Osp.*, February, 1892), after washing out the uterus, which had been curetted, with a solution of ichthyol in glycerine one to three, saw symptoms of general depression in his patient, which lasted for twelve hours, attended with pulse such as seen in tachycardia. The writer had used ichthyol in a hundred previous uterine cases without accident.

Abscesses in Pott's Disease —Dr. Burrell believes the following conclusions are warranted: 1. That efficient mechanical support of the spine is the prime factor in the treatment of caries of the spine associated with an abscess. 2. That under an expectant plan of treatment the abscess will, in many cases, disappear. 3. That the indication for operative interference is a steady or rapid decline in the patient's general condition. 4. That the operation should consist in thorough evacuation of the abscess, and the establishment of drainage from as near the seat of the disease as is practicable.—*Archives of Pediatrics*, May, 1892.

Exophthalmos in an Infant.—Dr. Philipsen (*Annal d'Oculist*, December, 1891) saw an infant of ten days with a pronounced displacement of the right eye forward and downward. It had been noticed two days after birth. A smooth, rounded tumor could be made out within the orbit, fluctuating, and painless on pressure. Without treatment this disappeared gradually and the eye regained its natural place, and three months later showed no signs. The diagnosis was cephalæmatoma, developed either between the periosteum and the orbital vault and between the dura mater and the vault, and having penetrated into the orbit by a congenital communication.

Gall-stone Fever.—The fever and chills attending the passage of gall-stones has at times so closely simulated intermittent fever that very early writers on the subject called attention to this condition. Dr. Schmitz brings up the question again (*Berlin. klin. Wochens.*, No. 37, 1891). He has found colic and jaundice in most cases, and when the former was about to begin there has been present distention and tenseness of the abdomen, and the pain has coincided with the rigor. Very rarely colic came first and fever appeared while it was still present. From fifteen to twenty-four hours after the fever, jaundice appears. The temperature may reach 105° F. or more, but usually not over 103.5° to 104.5° F. are noted. As a differential point from malaria, if the patient goes to sleep he awakens with mental confusion, headache, malaise, and weariness, and may even remain in a dazed condition for some time. If gall stones are not found in the dejections, if colic is absent, and jaundice alone is present, or even when this sign too is wanting, the existence of gall-stone disease may be looked upon as probable if, before the rigor, tympanites can be made out, and if, after the attack, a soporific state comes on.

Whipping in the Treatment of Hysteria.—Dr. O. Wiederhold, a director of the private sanatorium at Wilhelmshöhe, near Cassel, has just been sentenced to three months' imprisonment for administering a whipping to one of his patients. It appears that the wife of a gentleman occupying a high official position in Dresden entered Dr. Wiederhold's establishment suffering from marked hysteria. She was a very refractory patient, and gave great trouble by her habit of screaming for hours continuously when anything annoyed her. Dr. Wiederhold admitted that he had on several occasions beaten her with a thin stick, and that, one morning when she was in bed, he had lifted her nightgown and given her several cuts with a riding-whip across the body. Professor Uiczek, of Marburg, and Dr. Pellmann, director of the lunatic asylum at Bonn, were called as experts, and agreed in condemning corporal punishment such as that described as a therapeutic aid in nervous diseases.

A Slur on the Medical Profession of Chicago.—The *British Medical Journal* says: "Slow going Europe was much amused at the characteristic official method employed at Chicago to meet the unpleasant effect produced by the publication of the figures representing the epidemic and endemic prevalence of typhoid fever in that city, and the extensive pollution of the lake water with which the city is served. There were 2,000 deaths reported from typhoid fever in 1891, and 311 deaths from typhoid in January of the present year. There was also evidence that the sewage of a city of some one hundred and eighty thousand persons passes directly into the lake, and that further pollution is brought about by means of the Chicago River, which communicates with the Mississippi as well as Lake Michigan. The simple reply made to this was that the doctors did not know how to diagnose typhoid fever, and that probably not more than four hundred out of four thousand cases so recorded were correctly entered. We have been waiting with amused wonder for the response of the maligned medical faculty to this serio-comic retort, which would only be regarded as a bad and foolish joke in any other civilized city, whether of Europe or America. Meantime, it is instructive to note that instead of giving solidity or confirmation to the promise held out by Mr. MacCormach, the Commissioner in Great Britain, that the sources of water supply would be, in good time before the Exhibition, carried two miles further out into the lake, the *mot d'ordre* appears to be to give this significant hint to the doctors that for the future they had better register what they have been in the habit of recognizing as typhoid fever under some other name. This will not, however, diminish the mortality, nor will it add to the confidence with which future and, perhaps, more reassuring returns will be regarded by intending visitors to the Columbian Exposition."

Medical Examinations Before Marriage.—It is said that there is a law in Brazil compelling prospective brides and grooms to submit to a medical examination as a preliminary to a legal marriage. Such a law is theoretically excellent as a means to stamp out hereditary tendencies to disease and to prevent the transmission of certain maladies, like syphilis, to the offspring. But practically we fear love laughs at doctors just as well as at locksmiths.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery

New York, June 25, 1892.

A MODEL TO IMITATE.

THERE are a great many peculiarities reported of men of genius. Sir Isaac Newton was a vegetarian; General "Stonewall" Jackson thought one side of his body was heavier than the other, and always carried a weight in his pocket; Schopenhauer played the guitar; Erasmus would not eat fish, and Dr. Johnson never took a walk without touching the lamp-posts. But we learn that the peculiarity of Mr. Gladstone's greatness is more curious and subtle than that of any of his predecessors. Every bolus of food which he takes is chewed thirty-two times! Why thirty-two instead of thirty-nine, which is the number of the Articles, or thirty, which is the number of the days of the month, or some other number which has a specific significance, has not been explained. Perhaps some time the Grand Old Man will leave his Homeric and Celtic studies for an elucidation of these more serious problems.

We are, however, not disposed to quarrel with thirty-two. It is a good number, and one which ought to secure thoroughly pultaceous mastication, and a completely saturated insalivation, besides exercising the masseters, temporals, external and internal pterygoids, and securing time for a pleasing gratification of the sense of taste.

There are a great many things making up the admirable character of Mr. Gladstone which cannot be imitated, however desirable that might be. But his two-and-thirty method of mastication can be followed, and would have important influences upon the health and happiness of Americans, if it were done. Dyspepsia, biliousness, headaches, neurasthenia, insanity, and bad temper would decrease, and perhaps disappear. We commend the method of operation upon the food bolus adopted by Mr. Gladstone. If humanity imitates it we can truly say: *Exegi monumentum ære perennius*, no matter what becomes of the Irish.

THE CIRCULATION IN THE VERTEBRAL ARTERIES.

THE effect of ligating the carotids and the vertebral arteries was first studied by Sir Astley Cooper. He found that the carotids could be ligated without killing the animal if the operations were not done simultaneously. Ligation of both vertebrals was attended with more serious symptoms of cardiac and respiratory disturbance; subsequent experiments have shown that only with great care is it possible to ligate both vertebrals without causing death. It has been learned that the vertebrals preside over the cardiac and pulmonary functions, and that in addition their obstruction may lead to glycosuria and paralysis of the upper limbs. Girandeau and Hallopeau had a patient with an aneurism of the basilar artery. Every time he bent down his head his respiration was stopped and his heart was slowed.

This was a clinical demonstration of the effect of compression on the arterial supply of the vertebrals.

Dr. Dewèvre in the *Revue de Medecine*, May, 1892, contributes some new studies regarding the articulation of the vertebrals. Perhaps the most interesting point which he establishes is that regarding the relation of the carotids and the vertebral blood currents. These are, in a large measure, independent, yet have a reciprocal influence. The carotid arteries supply the cerebral hemispheres, the vertebrals the pons and medulla; one has to do with psychical and the other with somatic life; one may live without carotids but not without vertebrals.

Compression on the carotid causes an increase in the strength and tension of the vertebral blood-current. In the hippopotamus, as Gratiolet showed, the hyoid bone is so arranged that by muscular contraction it compresses the carotids, the vertebrals dilate, and the medulla and pons are flooded with blood. Other amphibious animals have a somewhat similar arrangement, enabling them to continue a long time under water without breathing. In man, when a vigorous heart-action drives an excessive amount of blood to the head, the thyroid gland dilates and presses on the carotid; this lessens the cerebral hyperæmia, but, if anything, invigorates the bulbar circulation. Another fact upon which Dr. Dewèvre insists is that it is very difficult to produce an anæmia of the bulbar circulation, or in any way to lessen its strength. It is this tenacity of the vertebral circulation which preserves the vitality of the bulb in persons who have been submerged for a long time. On the other hand, the bony canal, through which the vertebrals pass, mechanically prevents an excessive vascular dilatation, and explains he thinks, the rarity of aneurisms and hemorrhages in this vascular area.

The theory that any form of epilepsy is due to spasm of the bulbar arteries is certainly weakened if Dewèvre's statements are true. And it must henceforth be borne in mind that carotid compression, while limiting the flow of blood to the cerebrum, increases the flow to the medulla.

ACUTE RHEUMATISM.

THERE is at least one thing about which doctors agree, and that is, the drug which acts most surely in acute rheumatism. Dr. M. Baudouin has made a tour of the Paris hospitals and finds that all the physicians use salicylate of soda. Some give also bicarbonate of soda and antipyrin; but salicylate is the sheet-anchor. The mode of administration differs, however. Dujardin Beaumetz gives 15 grains every three hours; Talamon, the same amount every two hours; Straus gives 45 to 60 grains in single doses twice daily; Bouchard, 75 grains of the salicylate and 150 grains of the bicarbonate of soda daily. Barth, in some cases gives quinine and antipyrin, while Chauffard uses antipyrin alone, giving 60 to 120 grains

daily. Barié gives 30 grains three times a day, and Comby 15 grains every two hours.

In the New York hospitals larger doses than the above are often given. In Bellevue, 20 grains every two hours, for the first day, is usually prescribed. In St. Luke's, oil of wintergreen has been much used. Salol has been given also instead of the salicylate. Nothing has yet approached the salicylates in efficacy in the treatment of acute rheumatism. It is generally the septic and gonorrhœal cases only in which it fails. But there is still a wide divergence of opinion as to how to administer the drug so as to get its effects *cito, tuto, et jucunde.*

THE BISHOP AUTOPSY FARCE.

Our friend District-Attorney Nicoll has so thoroughly impressed the profession with his loyalty to scientific medicine that we are somewhat surprised to learn that the ridiculous charges in the Bishop case are still unsettled. Our readers will recollect that months ago there was a great hue and cry against Drs. Irwin, Ferguson, and Hance, of this city, for making an autopsy upon the body of Bishop while he was in a supposed trance. The accounts of the affair bristled with blood-creeping headlines of butchery by doctors, murder on the post-mortem table, and other equally complimentary reflections upon scientific motives, resulting in the indictment of the doctors by the grand jury and subsequent trial. It was then proved that the charge of dissection before death was an absurdity, and it was believed that the matter was settled. Now, however, a technical charge is made to the effect that the autopsy was made without due permission. As the patient himself requested it in the presence of witnesses, we are at a loss to understand what the legal interpretation of proper permission may mean. But law and justice are not always synonymous terms.

A FOUR YEARS' COMPULSORY COURSE.

The Harvard Medical School begins its Fall session by adopting a compulsory four years' course. Students in classical and scientical schools in which courses in anatomy, physiology, histology, and chemistry are taught can be admitted to advanced standing on passing an examination. This will virtually shorten the course to graduates of classical colleges, which is as it should be. The Harvard School deserves great credit for having the courage to take this step, and we trust it will be rewarded in the students it secures, and the reputation which the thoroughness of its training must bring.

Still, Medical Colleges who adopt the four years' course ought to exempt students which at the end of the third year secure hospital appointments, and this we believe is practically done at Harvard.

The Lamb and Syphilis.—An Italian physician is treating secondary syphilis by intra-muscular injections of lamb's serum, and reports good results therefrom. Why he has selected a lamb as the particular animal from which to obtain the serum is not apparent, unless it is that the lamb has always been regarded as the symbol of purity, and by extracting its virtue he hopes to counteract the effects of vice.—*Doctor's Weekly.*

News of the Week.

Woman's Medical College of the New York Infirmary.—Dr. William Oliver Moore has resigned from the Chair of Ophthalmology and Otology.

The Death of Dr. William R. Birdsall.—At a meeting of the Medical Board of the Manhattan Eye and Ear Hospital, held on June 10th, the following resolutions were adopted:

Whereas, It has pleased Almighty God to remove from our number Dr. William R. Birdsall, one of the physicians to this Hospital;

Resolved, That in bowing to His will we desire to express our esteem and love for Dr. Birdsall as our colleague and friend, and our sense of the loss sustained by the Hospital in the removal of one of our most faithful and efficient workers, who has made valuable contributions to the science of medicine;

Resolved, That the sincere sympathy of the Board be extended to his family in their deep affliction;

Resolved, That the Board in a body attend his funeral;

Resolved, That these resolutions be spread on the minutes of the Board, and be published in the Medical Record and the New York *Medical Journal*.—D. B. St. John Roosa, M.D., *President*; Charles H. Knight, M.D., *Secretary*.

Cholera is prevailing in Persia to an alarming extent.

The Late Dr. D. Hayes Agnew left an estate of about $250,000. He bequeaths to the University of Pennsylvania, $50,000, his work on surgery, his library and anatomical collections.

Dr. Theodore Meynert, Professor of Nervous and Mental Diseases in the University of Vienna, died on May 30, aged fifty-nine years. Professor Meynert was one of the most eminent anatomists and alienists of modern times. His contributions to the anatomy of the nervous system were numerous and original, and gave a great impetus to investigations in this line. He wrote a treatise on the anatomy and diseases of the fore-brain which embodies many of his researches.

The Medical Profession in Japan.—From statistics recently communicated to the Comité d'Hygiène Publique by Professor Proust, we learn that that go-ahead country Japan boasts 38,620 practitioners of medicine. This, with a population of 40,000,000, gives one professor of the healing art to 1,035 inhabitants. Unfortunately, 29,105 of these gentlemen are not provided with a diploma, and of the others many possess qualifications which would hardly command confidence in European countries.

The Spanish-American Medical Congress.—The four hundredth anniversary of the discovery of America by Columbus is to be celebrated in Spain next autumn, with much pomp and circumstance. The medical profession proposes to do honor to the occasion in its own way by holding a congress, in which it is expected that the whole Spanish-speaking profession will be represented. The Organizing Committee, in their circular of invitation, point out that Pablo Toscanelli, a Florentine physician, had much influence in inducing Columbus to embark on his memorable voyage, and Garcia Hernández, Physician to

Philip the Second, was consulted by the Spanish Court as to the feasibility of the explorer's plans. The labors of Juan the Second's physicians, Rodrigo and José, who were two of the most eminent geographers of the time, had smoothed the way for Columbus's enterprise. Two medical men, a physician and a surgeon, shared the dangers of his first voyage, and Chanca, who sailed with him in the second, made a study of the flora and fauna as well as of the diseases of the New World. Garcia Hernández himself commanded the scientific expedition organized by Philip the Second, and brought back a large quantity of observations, most of which seem to have been stowed away in official pigeon-holes at Rome, and forgotten. The Hispano American Congress will be held at Madrid in October next. The official language will be Spanish, but communications in English, French, Portuguese, and Italian will also be received. The work of the Congress will be carried out in five sections—History, Hygiene, Medicine, Surgery, and Pharmacology and Therapeutics. Among the subjects proposed for discussion in the Section of History are the following: The influence of certain physicians, antecedent to or contemporary with Columbus, on the discovery of America; popular medicine in America; had the discovery of America any importance in the epidemic development of syphilis in Europe? In the Section of Hygiene food for discussion will be found in such questions as yellow fever, the acclimatization of Europeans in America, precautions to be taken against malaria in hot countries, the domestic animals introduced by the Spaniards into America, and their influence on public health, etc. In the Section of Medicine the most promising topics are the comparative study of alcoholism in Europe and America, the neuroses which find specially favorable conditions for their development in America, animal and vegetable parasites of America in their relation to diseases of men and animals, the pathological predominance of the lymphatic glandular system in hot climates and the causes which produce it, etc. In the Section of Surgery there will be a debate on modifications in the course and in the treatment of syphilis, both in Europeans and in Americans, consequent on sudden changes from one continent to the other; the treatment of wounds, and the conduct of operations in America, especially in the tropical zone, will also be discussed. In the Section of Pharmacy and Therapeutics the programme of discussion includes the treatment of yellow fever, the therapeutic value of quinine, the differences in the treatment of malaria in Europe and America, and the improvements in pharmacology which have followed the discovery of America. Communications intended for presentation to the Congress should be sent to the General Secretary, Dr. D. Sinforiano Garán Mansilla, Magdalena 19, *Segundo, izquierda*, Madrid.—*British Medical Journal.*

The Reflex Club meets in Sacramento, Cal., and publishes acrimonious but instructive proceedings in the *Occidental Medical Times*. The club is at present at work over headaches, which Professor Fallopius. and Drs. Strabismus, Causticus, and Rectus, each claims as his own.

Medical Education of Women in Russia.—The Russian Imperial Council has by a large majority decided on the establishment of a Medical Institute for Women in St. Petersburg. The Municipal Council will contribute £16,000 for the purpose, the Ministry of Public Instruction, £7,000. the Ministry of War, £8,450, and the Society for the Maintenance of Medical and Pedagogic Instruction, £250. The municipal authorities will, besides, give the site both for the school and for the clinics in connection with it.

A Medical Princess.—A Myingoondine princess, granddaughter of the late Mindoon Min, King Theebaw's predecessor, is studying medicine at the Rangoon Hospital, with the view of qualifying herself to practise among her Burmese fellow-countrywomen. The princess, with other members of King Mindoon Min's family, was rescued from captivity by the British occupation of Burmah in 1885.

Reichmann's Disease.—Mathieu (*Arch. Gén. de Méd.*, May, 1892) relates the following case of permanent gastric hypersecretion followed by ulcer. A man, aged forty-two, dated his dyspeptic troubles from a reverse of fortune due to the Russo-Turkish war. He suffered from attacks of pain, typical of gastric hypersecretion, commencing about a couple of hours after food, and increasing for another two or three hours. The pain was often relieved by taking a little food, either solid or liquid. Sometimes vomiting put an end to the attack (see also "Epitome," March 5, 1892, par. 199). Four years ago he was much benefited by washing out the stomach. On admission there was marked gastric dilatation. The gastric juice contained an excess of hydrochloric acid. He was much improved by treatment, and was thinking of leaving the hospital, when he was seized one evening with pain in the epigastrium He died in two days' time of collapse. At the necropsy the stomach was much dilated and placed almost vertically, so that the greater curvature lay in great measure in the left mammary line, the lower part of the stomach near the pylorus being greatly distended, whereas the pylorus itself was nearly in the usual position. On the anterior surface, about two centimetres from the pylorus, there was a perforation big enough to admit the tip of the index finger. It had obviously been there some time. There was some general peritonitis, but apparently none of the contents of the stomach had extravasated, owing to the position of the perforation. Sections from the cardia showed that the coats of the stomach were thickened and the glands hypertrophied. In the region of the dilatation, near the pylorus, the changes in the mucosa were more marked. There was round-celled infiltration and the glands were dilated and cystic. In all cases of permanent hypersecretion there is gastric dilatation. It is evident that hypersecretion is compatible with a considerable degree of gastritis. The parts least affected secrete the gastric juice; those most diseased are digested. The round ulcer is one of the dangers of gastric hypersecretion, and for this reason passing the tube and washing out the stomach must be used prudently.—*British Medical Journal.*

The Society of the Alumni of Bellevue Hospital.—The following are the officers for the ensuing year: *President*, W. R. Townsend; *Vice-President*, Frederick H. Wiggin; *Secretary*, William N. Hubbard; *Treasurer*, Robert J. Carlisle.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE CHANGES IN THE BLOOD IN THE COURSE OF RHEUMATIC ATTACKS—THE DIFFERENCES BETWEEN RHEUMATIC ARTHRITIS AND RHEUMATOID ARTHRITIS—TWO NEW MEDICAL KNIGHTS—A STRANGE LAW CASE—THE LONDON COUNTY COUNCIL AND FEES AT INQUESTS.

London, May 28, 1892.

Rheumatism and rheumatic arthritis occupied the attention of the Medical and Chirurgical Society at its last meeting. A further communication on "The Changes in the Blood in the Course of Rheumatic Attacks" was brought forward by Dr A. E. Garrod (a son of Sir Alfred Garrod). The author gave an account of his observations on the variations in the number of white corpuscles and the character of the fibrin network in simple slide preparations of the blood. He agreed with M. Hayem that in acute rheumatism there was a distinct increase of white corpuscles—though never any extreme degree of leucocytosis. The highest number of white corpuscles observed was about twenty thousand per cubic millimetre. According to recent observers the average number in healthy blood was between six thousand and seven thousand. The increase of white corpuscles was found to bear a close relation to the amount of febrile disturbance. The increase was only trifling in amount in subacute cases and where there were conspicuous local manifestations without any marked rise of temperature. The increase of white corpuscles was rapid and took place at an early stage of the attack. When a relapse occurred a fresh increase of leucocytes was observed. The fall during convalesence might be either rapid or gradual. The number of blood platelets was usually increased during the period of convalesence. No noteworthy changes in the form or size of the red corpuscles was observed. Dr. Garrod disagreed with M. Hayem as to the value of the coarseness of the fibrin network in simple slide preparations of the blood of rheumatic patients as a diagnostic sign, and thought that it could only be of service as such in a limited number of cases. The counting of the white corpuscles was done with a Thoma-Zeiss hæmacytometer with a special pipette diluting only ten or twenty times. A 0 03 per cent. solution of acetic acid was employed for the dilution. In each observation fifty microscopic fields of known area were counted, the total area corresponding to 490.8 squares of Gower's hæmacytometer.

Dr. William Hunter referred to the importance of calculating the percentage of white to red corpuscles, as well as giving the absolute number of the former per cubic millimetre of the blood in rheumatic fever, as, in this disease, the diaphoresis must affect the concentration of the blood very considerably. The increase in leucocytes opened up an interesting speculation as to whether rheumatic fever was an infective disease, using that term in its widest sense. In all the infective diseases an increase of leucocytes was a very distinct feature, and was roughly proportional to the severity of the disease.

Dr. Habershon said he could confirm Dr. Garrod's observations as to the increase in leucocytes. The cause of such increase was still undiscovered. He had himself shown that the leucocytes were enormously increased in number during diabetic coma; other conditions, such as the introduction of alkaline carbonates and toxins into the blood, also increased the number considerably.

A communication on "Rheumatoid Arthritis and Rheumatic Arthritis," by Mr. Hugh Lane, of Bath, was then read. Mr. Lane reiterated his former conclusions, viz., that chronic rheumatic arthritis was an arthritis of rheumatic origin, while chronic rheumatoid arthritis was a constitutional disease of debility, invariably having a history of either phthisis or gout, or both. In rheumatic arthritis the existence of rheumatism was revealed by subacute attacks, and to these attacks the subsequent distinctive deformities were due. Rheumatic arthritis exhibited no marked neurosis, had no relation to osteo arthritis, was more confined to the joints, and was more a local than a constitutional disease; the heart was often affected; the reflexes were increased—especially late in the disease; muscular atrophy, if present, was a late symptom; the joints exhibited typical deformity, with no effusion, but presented the appearance of a solid enlargement of the joint area. Rheumatoid arthritis, on the other hand, was a constitutional disease with many neuroses; a peculiar anæmia and muscular atrophy were early and constant symptoms; reflexes were normal or diminished; the pulse was rapid and hard; and the joint areas presented typical fusiform swellings which develop later into the mushroom-shaped condition of osteo-arthritis. Mr. Lane said his later researches had confirmed his opinion as to these distinctions, and treatment had accentuated their importance. The manner of onset differed in the two diseases. Climate exerted more influence in rheumatic than in rheumatoid arthritis. The anæmia was more marked in the latter. All might suffer from rheumatoid arthritis, but in rheumatic arthritis the young seldom suffered and the rich claimed more exemption. Migraine, perverted taste, deafness, and other symptoms went a long way, in Mr. Lane's opinion, in establishing chronic rheumatoid arthritis as a disease separate from chronic rheumatic arthritis.

Sir Alfred Garrod said it was now thirty-two years since he had shown that there was a large class of cases which owed their origin to neither gout nor true rheumatism. There was no uric acid in the blood, but the joints were injured from the very earliest stage by ulceration of the cartilages, leading to absorption. Any debilitating affection—even mental depression—appeared to be an efficient cause. He still believed that acute rheumatism could start an attack.

Dr. Ord said he had arrived at different conclusions—perhaps because he approached the subject from a different point of view. He thought the term chronic rheumatic arthritis could be well applied to a limited number of cases in which chronic arthritis followed on acute rheumatism; such cases occurred in people rather under than over forty. There might be bony outgrowths around the joint without much change in the synovial membrane, and there was a tendency toward fibrous anchylosis. Rheumatic relapses were not common. The wasting of the muscles was usually out of proportion to the disease of the joints, and was the work of trophic nerves, to which also the joint disease was due. In several cases he had found central nervous changes in the anterior cornua of the cord. In many cases of progressive osteo-arthritis the inflammatory exacerbations were due to such different conditions as exposure to cold, emotional disturbances, and the menstrual periods. He had noticed symmetrical enlargements of the distal articulations during the menstrual periods, which partly subsided in the intervals. It was easy to conceive that the uterine hyperæmia disturbed the circulation in the cord, with consequent reflex irritation of the joints. It was important to assume as little as possible, and he thought "chronic osteo arthritis" was a better term than "rheumatic arthritis."

Mr. Lane then replied. In answer to a question from Sir Andrew Clark as to whether, in cases where struma had been present, he had ever found tubercle bacilli, he said the connection between rheumatoid arthritis and struma was not a direct one, but rather that the subject of it came of a strumous or gouty stock. He remarked that in rheumatic arthritis the enlargement about the joints preserved to a certain extent the shape of the joint; there was never any suspicion of fluid, and the resulting anchylosis was very firm. In rheumatoid arthritis the enlargements were often spongy; there was much deformity, and the anchylosis was never so firm as in rheumatic arthritis. Relapses were rare in rheumatoid arthritis, though exacerbations occurred during the menstrual periods and during times of excitement, as Dr. Ord had pointed out.

Anti-rheumatic treatment never did any good in this disease, but tonics were of the greatest benefit. The methods of treating the two diseases with the bath waters were similar, but only in early cases was good likely to result.

The *Gazette* published on the Queen's birthday contains the names of two civilian medical men, besides those of several medical men in the public services. Dr. Bateman, of Norwich, and Dr. George Johnson, of London, are the two medical men in question, and are each to receive the honor of knighthood. Dr. Bateman became qualified in 1849, and became M.D. at Aberdeen University in the following year He studied also in Paris, and enjoys the distinction of being a Fellow of the Academy of Medicine of Paris. He has made numerous contributions to medical science, and is perhaps best known by his work on "Aphasia." He is at present Senior Physician to the Norfolk and Norwich Hospital. Dr. George Johnson has been a member of the profession for half a century, for he took his M.B. degree at the University of London in 1842, obtaining the University Scholarship in Medicine. He proceeded to the M.D. degree two years later. He is a member of the Senate of the London University, Consulting Physician to King's College Hospital, and late President of the Royal Medical and Chirurgical Society. He is also one of the Physicians Extraordinary to the Queen. His published papers are numerous. His views on the pathology of Bright's disease are well known, and he has lately defended them with unabated vigor. His "Essay on Asphyxia," published in 1889, attracted some attention.

A remarkable law case has just been decided. A boy had his arm amputated at the Bolton Infirmary. The boy subsequently died, whereupon his father sued the house surgeon for the value of the limb removed and assessed it at ten pounds. The judge decided that the father had no property in his son or his son's body and non-suited the plaintiff.

It appears that there was an error in the statement lately promulgated that the County Council disallowed fees for the cleansing of bodies at inquests. They are merely revising the scale of fees and insisting that they shall be paid to the proper persons. It has transpired that a system of "sweating" has been going on.

PORRO OPERATION—SUCCESSFUL.

To the Editor of the Medical Record.

Sir: Having noticed reported in your journal of late several cases of abdominal section for saving fœtal and maternal life, I beg to add my quota from this somewhat remote portion of the continent.

The case was one of Porro's operation, with successful result for mother and child. The patient, a primipara, aged thirty-seven, had suffered for nine years with multiple fibroid tumors of uterus, chiefly sub-peritoneal. Before pregnancy began, her abdomen had attained the size of that of a woman in the ninth month. It having been decided that the child could not be born *per vias naturales*, patient was placed in a private hospital and a date about one week before expected time of confinement was fixed for the operation. Patient took ether well; there were only slight adhesions, and no special difficulties were experienced in the operative procedure. After removal of child an elastic ligature was used temporarily to control hemorrhage, this being replaced by a *serre-nœud* afterward. The blood lost was not of greater amount than in an ordinary confinement. Complete preliminary antiseptic precautions were taken, but hot water only was used during operation. The mass removed weighed about twenty pounds. The child, a fully developed female, weighed about eight and a half pounds and is doing well. The mother made an uninterrupted recovery, and is now, eight weeks after operation, able to go out, having walked about the building for two weeks past.

From experience of this case I am impressed with the feeling that abdominal section, either for removal of child only, or for the more radical operation, can never again be considered in the light of an experiment.

I am, yours truly,

J. F. Black, M.D.

Halifax, N. S., June 13, 1892.

OXALIC ACID IN CYSTITIS.

To the Editor of the Medical Record.

Sir: In the Medical Record of May 21st, page 575, appeared a clipping from *Le Bulletin Médical* of an article, by Dr. Renaud, recommending the use of oxalic acid in cystitis. I have not seen the original article, but, judging from the quotation, it would seem that Dr. Renaud claimed or assumed originality in the use of the acid for cystitis, but by referring to *The Therapeutic Gazette* of March, 1891, page 164, you will find the original prescription as proposed and used by me for the last five years.

I am, yours very respectfully,

A. W. Marsh, M D.

232 Main St., Westville, Conn., June 4, 1892.

SEX IN EDUCATION AN AFFAIR OF SOCIAL ECONOMICS.

To the Editor of the Medical Record.

Sir: One of the waning superstitions of the age is the fear that women of firm purpose and serious turn of mind may be greatly damaged by mental training and discipline, by anything that can turn natural aptitudes into useful and marketable products. Certain timorous mortals start and shrink lest women college graduates die before their time, go crazy, have fewer babies, perhaps not marry at all, forget *les convenance* in garb and ethics, and cease to cultivate personal beauty and the gentle amenities of every-day existence. These alarmists fear that somehow nature will be overthrown by the present and more benevolent order that prepares women for outside work, instead of allowing or forcing them to undertake it without any special preparation whatever. Fears that social confusion will arise out of it are groundless, and indicate a certain ignorance. Sex being the most significant fact in nature, it is reasonable to suppose that its influence will remain permanently the most potent factor in shaping any career. Women are the artists of this world, who preside over grace and beauty and the pleasures of life. "They reckon ill who leave me out," is true of nature everywhere. And it is not to be imagined that women, any more than men, can escape temperament. It is a ludicrous assumption that they are striving to do so by securing better market values, which is the true and only real meaning of higher education.

A college course for women, whether liberal or technical, is a test of mental integrity that insures to the earnest graduate a salary of $600, $800, or $1,000 to start with, and possibilities of a speedy increase, together with a definite and solid position. The industrial emancipation of women, like that of men, simply means emancipation from poverty, not from society nor from family relations. It is easily seen that the freer a woman is from poverty, the greater possibilities she has to raise marriage from the level of an economic compact to that of a social union. In other words, the educated, disciplined, capable woman will marry because of the happiness to be obtained from social and family life, instead of being actuated by more sordid or frivolous motives. Marriage is undoubtedly a high social institution, and greater freedom of both men and women will tend to elevate and improve it—not abolish it.

Just here the Record and its readers may justly ask, What has all this to do with medicine? And the writer will cheerfully and frankly reply, Nothing whatever: yet fully as much as tirades, dissertations, symposia of spe-

cialists, and such like matter, that too frequently abound in medical journals and rattle around in good space that otherwise might be filled with news.

The truth is, there is no such thing as the woman question. There is the progress of society, sentiment, and the personal equation. With the first, the physiologist has repeatedly shown himself unacquainted. With the second, he has nothing at all to do under any circumstances. And he never can know anything about the third, being an outsider. Yet the physiologist, even at this late day, might "spruce up" and become really valuable. Instead of harping upon facts that all the world knows about, as differences between men and women in angles, brain weight, construction of knee, distribution of brain substance, cerebral vascular supply, convolutional arrangement, etc., why not take a sensible view of the situation and decide what is to be done? This is the kind of science that is needed, the matter-of-fact excellence known as business, or the appreciation of values. Physiology alone never saved anything yet. It is commonsense that has a saving grace. The only question of any moment concerning sex in education is simply this: How, when, and where, can girls best receive the special, common-sense, latter-day training that is to increase and sustain both physical and mental powers; that is to fit them, with the least expenditure of force to bear the burdens of life easily; that is to make them so valuable in quality and expedients that they may always escape poverty, and remain forever capable of happiness, and efficient for usefulness? These are posers expressly designed for physiologists. And their careful consideration will help the world at large and greatly diminish the labors of medical readers in particular, for such investigation is not the work of a day, being quite outside the region of sentiment and personal preference. In this way, if in no other, the long suffering public may secure what is known as "a rest." Meantime the world goes on, duty continues, civilization advances, humanity improves and is happier, and life is ennobled and enriched—in spite of the physiologist.

Louise Fiske Bryson, M D.

38 West Thirty-eighth Street.

Women Medical Students in Russia.—The higher education of women in Russia has received a back-set, owing to the great influence of M. Pobedonoszens, Minister of Religion, with the Emperor. A few weeks ago, in answer to the general demand, the thirty-seven members of the Imperial Council presented a memorial to his Majesty, favoring the establishment of a separate school of medicine for women. It was said in the petition, among the reasons for the establishment of the institution, that there were annually eight thousand graduates of women's colleges in Russia. Owing to the distress in the country, the majority of these young women must give up ideas of marriage and would have to earn their own living. The profession of medicine would open up a profitable career to many of them. Five thousand roubles had been given to the capital for that purpose by wealthy citizens, the Minister of Instruction had expressed his belief in his ability to provide money for additional expenses, and the city authorities had promised to place the hospitals at the service of the women for clinical purposes. The Czar, it is said, looked upon the project with favor. But Pobedonoszens gained his ear. He reiterated the old theories regarding the proper sphere of women. He declared that the study of medicine led to a materialism, atheism, and nihilism, and thus to the destruction of the Empire. It should, therefore, never be permitted. Women were only fit for midwives and nurses. Pobedonoszens, to the chagrin of many people and the surprise of the imperial councillors and the Minister of Instruction, won his battle unaided. But the best friends of Russian women hope that the establishment of the medical school has only been postponed, and that Pobedonoszens will live to see his opposition unavailing.—*The Tribune.*

Varicella	0	0
Pertussis	0	0
Erysipelas	0	0
Leprosy	0	0
Mumps	0	0

Public and Pay Patients for State and Private Asylums.—In answer to numerous inquiries and to correct certain misapprehensions that now exist relative to the commitment and the care and treatment of the insane, the State Commission in Lunacy publishes the following:

1. *The Commitment of the Insane.*—By the statute no insane person can be admitted to an institution for the care and treatment of the insane except upon a medical certificate of lunacy, made jointly by two physicians, under a form prescribed by the State Commission in Lunancy. The form at present in use went into effect July 1, 1890, and commitments can now only be made under such form and upon blanks prepared and furnished by the State. These blanks can be obtained upon application to the State Commission in Lunacy, County Clerks, Superintendents of the Poor, and Superintendents of asylums or hospitals for the insane, both public and private. The medical certificate must be filled out strictly according to its terms in order to secure the commitment of a patient. There must be a final examination of the patient on the same day by both certifying physicians, although the final examination need not be conducted by each physician in the presence of the other. The date of the final examination is the date of the certificate. A patient can be admitted under such medical certificate at any time within ten days from its date, namely, the date of the final examination. While a patient may be admitted upon such certificate prior to its approval by a judge of a court of record, the patient cannot be detained more than five days without such approval, and therefore it is advisable, in order to avoid delays and a re-examination when such approval is not made within the required time, to procure the approval prior to the admission of the patient. The approval must be made by a judge of a court of record of the county or judicial district in which the patient resides. If, however, the patient has no fixed residence within the State, then the certificate may be approved by a judge of a court of record of the county or judicial district wherein such patient may be. A medical certificate prescribed by the Commission is an absolute requisite to the commitment of a patient; a judge, however, may require other and additional evidence. He may summon witnesses or additional physicians or may in his discretion call a jury in each case to determine the question of lunacy. Therefore, in order to avoid expense and delay, it is essential that great care should be taken in the preparation of such medical certificate. The statute provides that only such physicians as have been properly certified by a judge of a court of record, and only after a certified copy of their certificate of qualification has been filed in the office of the State Commission in Lunacy, can prepare such medical certificate. A medical certificate prepared by either one or both physicians whose certificate of qualification has not been filed in the office of the Commission

is void by statute and a re-examination of the patient must be had.

Section 2, Chap. 446, Laws of 1874 provides that "It shall not be lawful for any physician to certify to the insanity of any person for the purpose of securing his commitment to an asylum, unless said physician be of reputable character, a graduate of some incorporated medical college, a permanent resident of the State, and shall have been in the actual practice of his profession for at least three years. And such qualifications shall be certified to by a judge of any court of record."

Section 7 of Chapter 283, Laws of 1889, as amended by Chapter 273, Laws of 1890, provides that "One year after the date of the passage of this act (May 14, 1889), it shall not be lawful for any medical examiner in lunacy to make a certificate of insanity for the purpose of committing any person to custody unless a certified copy of his certificate has been so filed and its receipt in the office of the commission (State Commission in Lunacy) as above provided has been acknowledged."

2. *Public Patients.*—Public patients, except in the counties of New York and Kings, are required by the statute to be cared for in State hospitals situated within the hospital district in which they reside, the statute requiring that the State be divided into as many districts as there are State hospitals. A patient, however, who desires care and treatment in a State hospital situated beyond the hospital district in which he resides may be admitted to such hospital upon the following conditions:

a. When there is a vacancy.

b. In the discretion of the President of the State Commission in Lunacy and the Superintendent of the hospital to which the admission of the patient may be desired.

c. That any expense of removal beyond the limits of the hospital district in such case must be borne by said insane person's guardians, relatives, or friends, as the case may be.

This statute is liberally construed, and in no instance has the consent of the President of the Commission been refused or will such consent be refused in any proper case. When applications are made by mail or telegraph to the office of the Commission, in Albany, such consent will be promptly given.

3. *Public Patients from the Counties of New York and Kings.*—Public patients from the Counties of New York and Kings may be admitted to any State hospital within the State, with the consent of the authorities of such hospital and the Commissioners of Charities and Corrections of either of said counties.

4. *Private or Pay Patients.*—Private or pay patients may be admitted to any State hospital without reference to the hospital district in which they reside, upon the following conditions:

a. That there is room.

b. That the hospital authorities are willing to receive the patient.

c. That no patient shall be permitted to pay a sum in excess of ten dollars per week.

The maximum sum of ten dollars per week, to be charged for the care and treatment of a private or pay patient in a State hospital, was agreed upon at a conference of the State Commissioner in Lunacy and the Trustees and Superintendents of State hospitals. This limit of price was fixed upon in order that the rights of the dependent insane for whom the State hospitals were established, should not be encroached upon by patients who are able to pay a greater sum and who would require in return therefor a corresponding amount of room space and other allowances, which in view of the constant demand for accommodations for the dependent insane could not properly be accorded them. Each State hospital being established upon the principle of the greatest good to the greatest number, and recognizing no class distinctions, obviously no advantages, in the way of extra room space, etc., can properly be given, and especially in view of the fact that adequate and competen private care and treatment, both allopathic and homœopathic, can now readily be obtained for the non dependent insane in private institutions, under the supervision of the State, for ten dollars per week and upward.

5. *Private Asylums.*—All private institutions for the care and treatment of the insane are required by statute to be licensed by the State Commission in Lunacy, and the commission is empowered to revoke any such license in its discretion when proper cause exists therefor, and no insane person can be committed to any institution, retreat, home, or sanitarium, which is not so licensed.

The following is a list of the licensed private institutions for the insane, with the name of the physician in charge, the location and the minimum sum charged per week:

Institution.	Physician in Charge.	Location.	Minimum Rate per Week.
Bloomingdale Asylum	S. B. Lyon	New York	$5 00
Providence Retreat	Harry A. Wood	Buffalo	6 00
Marshall Infirmary	J. D. Lomax	Troy	5 00
Long Island Home	O. J. Wilsey	Amityville	10 00
Brigham Hall	D. R. Burrell	Canandaigua	10 00
*St. Vincent's Retreat	J. A. Underhill	Harrison	10 00
Sanford Hall	J. W. Barstow	Flushing	25 00
*Dr. Wells's Sanitarium	T. L. Wells	Brooklyn	10 00
Dr. Combes's Sanitarium	R. C. F. Combes	Woodhaven	10 00
Dr. Choate's House	G. C. S. Choate	Pleasantville	75 00
Dr. Parsons's House	R. L. Parsons	Sing Sing	75 00
Falkirk	J. F. Ferguson	Central Valley	20 00
Vernon House	W. D. Granger	Bronxville	35 00
Breezehurst Terrace	D. A. Harrison	Whitestone	20 00
Waldemere	E. N. Carpenter	Mamaroneck	25 00
The Pines	Fred. Sefton	Auburn	20 00
Glenmary Home	J. T. Greenleaf	Oswego	10 00
Dungarthel	H. R. Styles	Lake George.	25 00

* Receive female patients only.

Caterpillars as a Cause of Urticaria.—Laudon, in *Virchow's Archiv.*, vol. i., 25, has described an epidemic of urticaria at Rahlberg, which coincided with the appearance of caterpillars on the walls of dwellings. The cause of urticaria is not only in the formic acid, but more particularly in the hairs of the back of the caterpillars.

The International Temperance Congress.—The preliminary programme of the Fourth International Congress for the Prevention of the Abuse of Alcoholic Drinks, which, as has already been announced, is to meet at The Hague on September 8th, has been issued. The following are the subjects proposed by the Organizing Committee for discussion: 1. "Alcohol in its Moral, Hygienic, and Medical Relations;" 2, "The Preventive and Educational Measures in Use for the Repression of the Abuse of Alcoholic Drinks (Associations, Meetings, the Press, Amusements for the People); and 3, "The Compulsory Means which can be Employed by the State and the Community for the Suppression of Drunkenness."

An Aggressive Hotel Doctor.—An alleged physician of Washington, D. C., has sued several lady guests at a hotel for medical services. They claim that his services were forced on them and that he prescribed medicine voluntarily, telling them they were sick and needed it. One lady protested that she was not sick, did not need any medicine, and if she did, she had a regular physician, and could consult him. Another was not a little annoyed by his insisting on removing freckles from her face.—*Medical Standard.*

Disinfected Second-hand Clothing.—The medical department of the Ministry of the Interior in Russia has issued an order that all second-hand articles put up for sale must be disinfected and provided with labels testifying to the act of disinfection. The police surgeons are to be charged with the duty of enforcing this order, and all second-hand articles not provided with the proper testimonials will be confiscated.

Practical treatise on the diseases of the ear, including a sketch of aural anatomy and physiology, by D. B. St. John Roosa, M.D., LL.D., 327.
Précis d'assistance aux opérations; préparation du malade et des instruments, anesthésie, soins consécutifs, par le Dr. Paul Thiéry, 583.
Prescriber's Pharmacopœia, a synopsis of the more recent remedies, officinal and unofficinal, with a therapeutic index and a résumé of the British Pharmacopœia additions, 1890, by a member of the Pharmaceutical Society of Great Britain, 356
Prescribing and treatment in the diseases of infants and children, by Philip E. Muskett, 412.
Principles of bacteriology; a practical manual for students and physicians, by A. C. Abbott, M.D., 412.
Ptomaines, leucomaines, and bacterial proteids; or, the chemical factors in the causation of disease, by Victor C. Vaughan, Ph.D., M.D., and Frederick S. Novy, Sc.D., M.D., 272.
Pulmonary tuberculosis, by R. W. Philip, M.A., M.D., F.R.S.E., 216.
Recent materia medica; notes on the origin and therapeutics, by F. Harwood Lescher, F.C.S., 244, 271.
Records of the Association of Acting Assistant Surgeons of the United States Army, A.D. 1891, edited by W. Thornton Parker, M.D., 75.
Saunders's pocket formulary, by William M. Powell, M.D., 244.
Sketch of surgical history (after Hecker), by John Hund, M.D., 76.
Surgical anatomy for students, by A. Marmaduke Shield, M.B. (Cantab.), F.R.C.S., 524.
Surgical diseases of the ovaries and Fallopian tubes, including tubal pregnancy, by J. Bland Sutton, F.R.C.S., 582.
Syllabus of the obstetrical lectures in the Medical Department of the University of Pennsylvania, by Richard C. Norris, A.M., M.D., 244.
Syphilis in ancient and prehistoric times, by Dr. F. Buret, Paris, France, translated from the French, with notes, by A. H. Ohmann Dumesnil, M.D., 522.
System of practical therapeutics, edited by Hobart Amory Hare, M.D., assisted by Walter Chrystie, M.D., vol. i., 327
Text-book of comparative anatomy, by Dr. Arnold Lang, with a preface by Professor Ernst Haeckel, translated into English by Henry M. Bernard, M.A. Cantab., and Matilda Bernard, part i., 523.
Text-book of nursing, for the use of training-schools, families, and private students, compiled by Clara S. Weeks-Shaw, 583.
Text-book of ophthalmoscopy, by Edward G. Loring, M.D., edited by Francis B. Loring, M.D.; part ii., diseases of the retina, optic nerve, and choroid, 216.
Text-book of physiology, by M. Foster, M.A., M.D., LL.D., etc., 356, 523.
Text-book of practical anatomy, by Henry C. Boenning, M.D., 244.
The doctor's ledger, copyrighted and published by C. A. Price, 244.
Traité pratique et philosophique du pied-bot, par E. Duval, Lauréat de l'Académie des Sciences (Institut de France), 524.
Transactions of the American Association of Obstetricians and Gynecologists, vol. iv., 524.
Transactions of the American Surgical Association, vol. ix., edited by J. Ewing Mears, M.D., 524.
Transactions of the Association of American Physicians; sixth session, held at Washington, D.C., September 22 to 25, 1891, vol. vi., 356.
Transactions of the Medical and Chirurgical Faculty of the State of Maryland, 524.
Treatise on Bright's disease of the kidneys; its pathology, diagnosis, and treatment, with chapters on the anatomy of the kidney, albuminuria, and the urinary secretion, by Henry B. Millard, M.A., M.D., 581.
Treatise on diseases of the lungs and pleura, by the late Wilson Fox, M.D.,

Book Notices:
F.R.S., edited by Sidney Coupland, M.D., F R.C.P., 439.
Treatise on gynecology, medical and surgical, by S. Pozzi, M.D., translated from the French edition under the supervision of, and with additions by, Brooks H. Wells, M.D., 411.
Treatise on the ligation of the great arteries in continuity, with observations on the nature, progress, and treatment of aneurism, by Charles A. Ballance, M.B., M.S. Lond., F R.C.S., and Walter Edmunds, M.A., M.C. Cantab., F.R.C.S., 522.
Under the Southern Cross; a guide to the sanitariums and other charming places in the West Indies and Spanish Main, by William F. Hutchinson, A.M., M.D., 356.
Untersuchung des auswurfs auf tuberkelbacillen, von Dr. Eugen Czaplewski, 272.
Wood's medical and surgical monographs, vol. xii., No. 3, 328.
Wood's medical and surgical monographs, November, 1891, 328.
Year-book of treatment for 1892, 583.
Bowman, Sir William, death of, 530.
Brain, abscess of, following otitis media, 471, 658; and its envelopes, general principles of the surgery of the, 663; ramrod through the, 382; removal of clots from the base of the, 578; subdural intra-cranial hemorrhage without fracture, 541; the medullated cortical fibres with the osmium-copper-hæmatoxylin stain, 288; thrombosis of cerebral sinuses 187; two cases of abscess of successfully treated by opening the skull and drainage, 220.
Brains versus drugs, 592.
Brannan, John Winters, a study of typhus fever, clinical, pathological, and bacteriological, 713.
Breast, abscess of, and tuberculosis, 708; compression for swollen, 654; fibrous tumor of the, 589; recurrence of cancer of the, 225; treatment of abscess of the, 14.
Breasts, diffuse hypertrophy of, 544.
Bremner, W. W., ulcers of the leg and varicose veins, their treatment by a new and simple method, 400.
Bridges, W. O., stricture of the urethra in the female, and reflex neurosis from urethral stricture in the male, 516.
Broadbent, Dr., attendance of, on the Prince of Wales's sons, 161.
Brom-æthyl narcosis, 691.
Bromidrosis of the feet, 607.
Bromoform, administration of, 243.
Bronchitis, of children, the harm of nauseating expectorants in, 138; plastic, 336.
Broncho-stenosis, syphilitic, in children, 588.
Brown, Edward J., a new baby incubator, 446.
Brücke, Ernst Wilhelm, death of, 75; last works of, 660.
Brush, Arthur C., the blood-changes in the malarial fevers, 66.
Bryson, Louise Fiske, sex in education an affair of social economics, 724.
Bubo, application for, 607; scarlatinal, 491.
Buchanan J. R., mechanical control of the circulation, 82.
Bulkley, L. Duncan, the non-contagiousness of leprosy, 276.
Bull, Charles Stedman, operative treatment of detachment of the retina by Schöler's method, with a report of five cases, 62.
Burnham, G. Herbert, remarks on the operation for secondary cataract, 461.
Burns, Dawson, ether as a stimulant, 531.
Burns, internal lesions after, 98; treatment of, 222.
Burrall, F. A., a suggestion with regard to spraying the nasal cavities, 308.
Burton, Augustus J., fracture of the femur from muscular action, 547.
Business principles in medical practice, 47, 48, 72.
Butter, a test for, 384.

C

Cæsarean section repeated on same woman after six years, followed by recovery, with a living child, 538; successful case of, 534; two successful cases of, 158.
Calculus, biliary, 191; salivary, 28.
Campbell, Henry F., death of, 45.
Cancer, alcoholic injections for, 550; and cancerous diseases, Morton lecture on, 647; caustic treatment of, 175, 328; electrical cure of, 549; epithelial, of the kidney, 463; mode of treatment of, by Dr. Adamkiewitz, 269; of the breast, morbid changes found associated with the, 135; of the breast, recurrence of, 225; of the intestines, 418; peripheral neuritis in, 15; primary, of the bladder, 472; transmissibility of, 544.
Cannibal therapeutics, 521.
Carbuncle, boric acid in, 211.
Carpenter, Alfred, death of, 224.
Carson, Edwin, tumor of the vocal cord—removal, 252.
Cartwright lectures for 1892, 197, 253, 449, 533.
Cascara sagrada as a tænicide, 576.
Case, Samuel H., obituary of, 132.
Castration for neuroses and psychoses in the male, 43.
Cataract extraction, antisepsis in, 576; methods of, 437; new procedure of, 166; 136 cases of, 121; secondary, 461.
Caterpillars as a cause of urticaria, 726.
Catheterization of women, 446.
Celluloid buttons, danger of, 648.
Cerebral sinuses, thrombosis of, 187.
Chambers, Talbot R., compression in the cure for swollen breast and for swollen testicle—two new appliances, 654.
Chancre of the tongue, 279.
Chancroid, inoculation of, 293; intra urethral, 590.
Chapman, H. W., the treatment of favus, 558.
Chappell, Walter F., europhen in the treatment of throat and nose diseases, 462; treatment of œsophageal stricture by permanent tubage, 205.
Cheesman, Hobart, vis protectrix naturæ in the vegetable world, and its relation to therapy in the animal world, 164.
Cheesman, Timothy Matlack, a study of typhus fever, clinical, pathological, and bacteriological, 713.
Chemotaxis, 438.
Chicago, sanitary condition of, 409, 464, 558, 676.
Chilblains, ulcerated, 491.
Childbed, embolism of the pulmonary artery in, 234, 245.
Childbirth complicated by facial erysipelas, 691; interference in delayed, 696.
Childhood, cerebral atrophies of, 85; headaches of, 19.
Children, conical stump following amputation in, 527; convulsions in, 575; erythema nodosum in, 575; incontinence of urine in, 13; meningitis in, 585; nasal catarrh in, 158; the harm of nauseating expectorants in the bronchitis of, 138; ununited fractures in, 196.
Chinese bone setters, 59.
Chloralamid, 575.
Chloranæmia, therapeutics of, 152.
Chloroform and ether, 347.
Chloroform, comparative action of the different brands of, 712; deaths from, 78, 437; notes on the use of, 585.
Chlorosis, scarification of the os uteri in, 488; treatment of, 280.
Cholera among sharks, 430; coffee in, 84.
Chorea and rheumatism, relation of, 588; and rheumatism, seasonal relations of, 642; hereditary, 281; in the Charité polyclinic, 126.
Chronic diseases, methodical treatment of, 156.
Chyluria, 211.
Cincinnati Obstetrical Society, officers of, 153.
Circulation, mechanical control of the, 82.
Circulatory diseases, distribution of, in the United States, 241.
Claiborne, John Herbert, Jr., curious formation in the vitreous humor, 127.
Clamps for use in abdominal surgery, 505; broad-ligament, for use in vaginal hysterectomy, 334.
Clarence, Duke of, cause of the death of the, 712.
Clayton, Oscar, death of, 224.
Clements, George Place, a new surgical needle, 503, 617.
Climacteric, veratrum viride for the palpitations and hot flashes of the, 693.
Clothing, disinfected second-hand, 726.
Clover's crutch, an improved, 363.
Club-foot, open incision for, 157; practical points in the treatment of, 649.
Coca, formula for a wine of, 607.
Cocaine habit, cure of the, 417.
Cocktail habit, 587.
Cod-liver oil, the best way to give, 439.
Coffee in cholera, 84.
Cohnheimoma, 321.
Cold, treatment of a, 113, 293.
Colic, hepatic, 718.
College of Surgeons and its members, 223.
Collins, Joseph, electrical injury followed by deltoid paralysis and traumatic neuroses, 69.
Colorado, disadvantage of exercise in, 382.
Color-blindness and a practical remedy for it, 577.
Colotomy, comparative value of inguinal and lumbar, 669.
Colpo-perineorrhaphy, 701.
Communion, the hygiene of the, 264.
Congenital dislocation of the hip, a new treatment of, 240.
Constipation, Dover's powder in, 222; mechanical treatment of, 279; treatment of habitual, 576.
Consumptives, the Trans-Pecos country as a winter health resort for, 306.
Contagious diseases, weekly statement, 28, 56, 84, 112, 139, 167, 196, 224, 252, 279, 306, 336, 391, 420, 447, 504, 560, 591, 620, 648, 677, 711, 725.
Convulsions cured by trephining, 320; in children, 575.
Convulsive tic, nature and treatment of, 236.
Corns, application for, 222.
Coroner system in New York, suggestions in regard to reform in the, 57.
Corrosive sublimate, danger of blue-colored tablets of, 677.
Corsets, gastric noises caused by, 352.
Coryza, acute, snuff for, 718; and the axis of astigmatism, 634.
Costabelle as a health-resort, 79.
Crane, Augustin A., leprosy and a fish diet, 363.
Craniotomy, linear, for dementia epileptica, 626; versus delivery through the abdominal walls, 697.
Cranial gap filled by celluloid plate, 357.
Creator, Galen's hymn to the, 686.
Creosote in the treatment of pulmonary phthisis, 229, 402; poisoning by, 456.
Credé, Professor, death of, 410.
Cremation in Berlin, 196; in France, 131; in Paris, 384.
Cretinism, sporadic congenital, 556.
Crime, physiological view of, 124.
Croup and diphtheria, diagnosis of, 378.
Crow, J. J., burnt flour as a dry dressing for ill-conditioned wounds, erysipelas, etc., 591.
Crumley, Harry, death of, 268.
Cuban medical degrees, 466.
Culver, Everett M., an extraordinary effort of nature to relieve an intussusception, 511.
Cystic duct, rupture of the, 246.
Cystitis, acute gonorrhœal, 293; medical treatment of, 17; treatment of, 448, 575, 718, 724.
Cystoscope, cases illustrating some difficulties in the use of the, 24.

D

Dana, Charles L., the nature and frequency of inebriety, with remarks on its treatment, 309.
Dandruff, pomade for, 222.
Darwinism, Virchow on, 298.

Dawbarn, Robert H. M., considerations upon medical hemorrhage surgically treated, with a successful case, by a new technique, of saline infusion for severe hemorrhage, 1, 24; hot saline infusion, arterial, without cutting, 275.
Dead Sea, microbes in the, 127.
Deafness, liquid vaseline for, 221.
Death certificate, a curious, 168; penalty, abolition of the, 159.
Déclat, Dr., the antiseptic treatment of tetanus, 162.
Defecation by the mouth, 46.
Degenerates, abnormities in, 183.
Dementia epileptica, linear craniotomy for, 626.
Dennis, Frederick S., recurrence of carcinoma of the breast, 225
Deposits, rapid method of collecting, for microscopic examination, 248.
Dermatol and iodoform, comparison between, 222.
Desemoid tumors of the abdominal walls, 668.
Dessar, Leonard A., a new nasal electrode, 618.
Diabetes, a new aliment for use in, 711; care of the teeth in, 491; experimental pancreatic, 13; from removal of the pancreas, 542; jambul in, 241; new clinical form of, 71; recent researches in, 223.
Diagnosis, a mistake in, 352.
Diarrhœa, chronic, causation and treatment of, 340, 358; novel cure for, 636.
Digestant, a new vegetable, 308.
Dime museum wedding, 417.
Diphtheria, and croup, diagnosis of, 378; chemical pathology of, 711; digestion of, 518; mercurial inunctions in, 576; prevention of, 473, 718; simulating simple angina, 554; tar and turpentine vapors for, 156; treatment of, 28, 222, 419; treatment of, in Paris, 607.
Disinfecting station in Baltimore, 586.
Disinfection of food, 616.
Dislocation, compound, of the ankle, recovery without suppuration from, 312; congenital, of the knee, 333.
Dispensary patients, advertising for, 183; question, 476, 581, 635, 637, 712.
Dissection, a bill to prevent, 409.
Diuretin, 718.
Doctor, the, and good roads, 609; the, and the priest, 73, 104; of pharmacy, degree of, in Munich, 611.
Dog-serum in phthisis, 550
Donlin, Philip, death of, 695.
Dosage, duodecimal system of, 409.
Douglas, Richard, intestinal obstruction, 538.
Dowd, Charles N., fibrous mammary tumors, 434.
Dowling, John W., death of, 154.
Drainage in abdominal surgery, 160.
Draper, Joseph, death of, 379.
Dropsy, essential, 549; renal, discussion on, 645, 673.
Druggists' check system, 213.
Drugs, specific action of, 586.
Drunkenness and fracture of the skull, 351.
Drzewiecki, Joseph, a contribution to the treatment of malignant growths, 91.
Dubois, Abram, memorial pavilion to, 580.
Duodenal indigestion, 179.
Duodenum, perforating ulcer of the, 525.
Dysentery, amœbic, 666; etiology and pathology of, 640; symptoms of, 641; treatment of, 607, 641.
Dyspepsia, acid, formula for, 222.
Dysphagia in pleurisy with effusion of the left side, 112.

E

Eagleson, J. B., birth of child during sleep of mother, 677.
Ear, disease of, brain abscess from, 658; instruments, some new, 618; treatment of chronic purulent inflammation of the middle, 618.
Ears, perichondritis auriculæ of both, 148.
Earache, relief of, 576.
Earl, the, and the doctor, 577.
Earle, Pliny, obituary of, 611.
Eclampsia, puerperal, treatment of, 13.
Écraseur, a modified nasal, 278.
Eczema, creoline in, 576; epilemic, 25; of the scalp, formula for, 222; relief of the itching of, 620; treatment of, 491.
Edson, Cyrus, as Sanitary Superintendent of the Health Department, 495.
Education, medical, 52.
Egan, R. R., recovery, without suppuration, from a compound dislocation of the ankle, in a patient of forty-five, 312.
Egypt, the insane in, 573.
Eight-hour movement, science and the, 695.
Einhorn Max, achylia gastrica, 650; therapeutic results of direct electrization of the stomach, 116, 142.
Elbow, ligamentous new formation after excision of the, 527.
Electrical execution, abolition of, 183; and the healing art, 524; the electricians on, 168.
Electrical injury followed by deltoid paralysis and traumatic neuroses, 69.
Electricity, direct application of, to the stomach, 116, 142; therapeutic value of, 465.
Electrode, a new electro-therapeutic, 536; a new nasal, 618; for positive galvanocauterization of the uterus, 676.
Electrolysis, removal of superfluous hair by, 209.
Electro-therapeutist, some new additions to the armamentarium of the, 617.
Ellis, R., a case of varicose abdominal veins in a boy of sixteen years, 109
Embalming, a law to regulate, 381.
Embolism of the pulmonary artery in childbed, 234, 245.
Emin Pasha relief expedition, ulcer of the, 43.
Emmet, Bache, broad-ligament clamps for use in vaginal hysterectomy and drainage-trocar, 334.
Endometritis, drainage of the uterus in, 49; treatment of, 157.
Endometrium, drainage in the treatment of diseases of the, 160; micro-organisms in the diseased, 699.
Engel, Hugo, dementia epileptica—improvement of this form of mental impairment following linear craniotomy, 626.
English, W. T., the singer's thorax, 261.
Enterectomy by a novel method, 708.
Enterostomy in intestinal obstruction, 441.
Enuresis, folk-lore remedy for, 620; treatment of, 99.
Ephedra vulgaris, 491.
Epilepsy, bacillus of, 610; borate of sodium in, 127, 576; craniotomy for, 85; diet and exercise in the treatment of, 587; laryngeal, 299.
Epileptics, Ohio State asylum for, 660.
Epithelioma of the lip, 589.
Erysipelas, a case of, 108; recurrent, 347; treatment of, 222.
Erythema multiforme in typhoid fever, 347.
Erythema nodosum in children, 575.
Esocarde, the, 44.
Ether and chloroform, 347; as a stimulant in a temperance hospital, 383, 531; drinking, 410; warm, as an anæsthetic, 47.
Etiology of disease, certain points in the, 645.
Europhen in throat and nose diseases, 462.
Evans, Sheldon Guthrie, favus and its treatment, 490.
Evolution in medicine, 661; present problems in, 197, 253, 533.
Exalgine, 180, 347.
Examinations, State medical, in New York, 19; State medical, in Ohio, 20.
Exanthem, a mixed, probably scarlatinous, 349.
Execution, abolition of electrical, 183.
Exophthalmos, 448, 492, 719.
Extremities, consecutive amputation or resection in serious injuries of the, 528.
Eye, conditions demanding excision of the, 707; curious formation in the vitreous humor, 127; relief of pain in, by the hot-box, 420; traumatism of, followed by immediate blindness, 191.
Eyelids, gouty, 177; soap in affections of the, 718.
Eye-strain, significance of, 42.

F

Fæces, retained, 666.
Falconer, R. Craig, double synchronous amputation of the thigh for gangrene in a case of chronic nephritis—complete recovery, 108.
Famine and typhus in Russia, 592.
Fancher, P. V., the dose of paraldehyde, 137.
Father, when is a man a? 693.
Favus, three varieties of, 544; treatment of, 490, 558.
Fee, the question of a, 692.
Femur, fracture of, from muscular action, 547.
Féréol, Louis Felix Henri, death of, 46.
Fernandez de Ybarra, A.M., a case of poisoning with phenacetin, 108; Cuban medical degrees, 466.
Fevers, eruptive, relief of itching in, 576.
Fibrin ferment as a styptic, 591.
Fibro-sarcomatosis, 348.
Filaria sanguinis hominis, 497.
Fleas, how to rid a house of, 308.
Fleischman, David, death of, 155.
Flint Club of Baltimore, 382.
Flour, burnt, as a dry dressing, 591.
Folk medicine in Russia, 689.
Food, a new, 168; probable errors of investigations of, 681.
Foot-ball casualties in England, 620.
Foot-warmers, 175.
Forest, W. E., a new method of artificial respiration in asphyxia of the new-born, 393.
Foster, Matthias L., application of antisepsis in ophthalmic and aural surgery, 686.
Fowl language, 620.
Fracture, compound, treatment of, 159; of the humerus, treatment of, 702; of the radius, treatment of 703; ununited, application of the sclerogenic method to the treatment of, 550; ununited, in children, 196.
France, caring for infants in, 407; foreign physicians in, 408.
Free, Spencer M., the country way of doing it, 446.
Freeman, Edward A., death of, 352.
French army, first aid to the injured in the, 448.
Freudenthal, W., poisoning by creosote, 456.
Fritsche, Gustav, death of, 243.
Frost, E. F., an odor in influenza, and coexistence of the disease with other infections, 210.
Früh, Carl D. S., scarlet fever followed by typhoid fever, 691.
Fuchsin bodies and cancer, 637.
Fumigation, death from, 314.
Furuncle, boric acid in, 211; treatment of, 576.
Furunculosis, infection in, 448.

G

Galen's hymn to the Creator, 686; use of medicines, 560.
Gallacetophenon in skin diseases, 279.
Gall-bladder and ducts, surgery of the, 667.
Gall-stone, expulsion of an immense, under the action of chloral, 587; fever from, 719; impacted, 332.
Gangrene, senile, early high amputation in, 158.
Gasserian ganglion, removal of the, 75.
Gastritis, catarrhal, 666.
Gelsemium as a therapeutic agent, 591.
Generation, rapid, 520, 677.
Genital organs, total absence of, 41.
Gentlewoman's effrontery, a, 464.
German army surgeons, post-graduate course for, 591.
German Congress of Internal Medicine, 637.
Germany, freedom of practice in, 265.

Gestation, ectopic, *see* pregnancy, extra-uterine; relation of the duration of, to legitimate birth, 696.
Gibney, V. P., the complications and sequelæ of tuberculous lesions involving the joints, with a discussion on the most efficient management, 344, 357.
Gil, R. Martin, two new clamps for use in abdominal surgery, 505.
Gleet, injection for, 607.
Glottis, treatment of spasm of the, 160.
Glycerine suppositories, 576.
Goitre, exophthalmic, 492; exophthalmic, in an infant, 719; exophthalmic, treatment of, 448.
Gonorrhœa, abortive treatment of, 347; new treatment for acute, 323; prophylaxis of, 407.
Gordon, Eliot, the dose of paraldehyde, 136.
Gosweiler, A. Van Hoff, a physiological view of crime, 124.
Gout, treatment of gastralgia in, 718.
Graves, Helen T., death of, 578.
Graveyard insurance, wholesale, 408.
Greek, a course of, for students who cannot go to college, 717; modern, as the language of science, 324, 476.
Greene, J. L., treatment of pneumonia, 141.
Gross, Samuel D., monument to the late, 494.
Groups, theory of, 44.
Growing fever, 182.
Guaiacol in tuberculosis, 101, 295.
Guild Misericordia, 502.
Gynecological operations, combined, 700.
Gynecological tinkering, 45.

Paracresotic acid, 409.
Paraldehyde, the dose of, 27, 195, 136, 242.
Paralysis, bulbar, contribution to the study of, 477; cured by trephining, 320; functional, 507; in childbood, craniotomy for, 85; infantile spinal, necessity for early mechanical treatment of, 122.
Paraplegia from extra dural tumor of the spine cured by operation, 290; syphilitic, 285.
Paresis of adolescence, 324.
Paris, scandal at the Faculty of Medicine of, 680.
Parker, Edward F., medical education, 52.
Parker, Thomas, forward dislocation of the radius and its reduction, 517.
Parker, W. M., the hygiene of the Holy Communion, 264.
Parker, W. Thornton, the Guild Misericordia, 502.
Parrot epidemic, 521.
Partridge, Edward L., embolism of the pulmonary artery in childbed, 234.
Parturition in hypnotic sleep, 100.
Pasco, Ferdinand M., death of, 519.
Pasteur Institute in Paris, a visit to the, 680.
Patellar ligament, elongation of, as a factor in the production of certain knee troubles and difficulties of locomotion, 59.
Pease, Charles G., pyorrhœa alveolaris often diagnosed as facial neuralgia, 178.
Peck, Washington F., death of, 102.
Peliosis rheumatica, 574.
Pelvic inflammation in women, 239.
Pelvic peritonitis, microscopical studies in, 597.
Pelvic surgery, influence of delayed and incomplete operations upon mortality in, 699.
Pelvic sinuses, treatment of, 21.
Penis, fracture of the, 320.
Penrose, George H., the treatment of pulmonary tuberculosis by creasote, 402.
Pental, 633.
Perichondritis auriculæ of both ears, 148.
Perineum, complete laceration of, without rise of temperature, 251; how to save the, 194.
Peritoneal cavity, caution to be observed in douching the, 278; removal of a glass rod, six and one-half inches in length, from the, 513.
Peritoneum, tolerance of the, 609.
Peritonitis, congenital, 312; from gallstones, 667.
Perityphlitis, 106; suppurative, with rupture into the bladder and rectum, 93. *See* also Appendicitis.
Perkinism, 280.
Peskind, A., remarks on functional paralysis, 507.
Pessary, the cylindrical vaginal tampon, versus other pessaries, 482; worn for twenty years, 78.
Peterson, Frederick, the insane in Egypt, 573.
Phagocytes and London policemen, 101.
Phagocytosis, 111; and immunity, 301, 389, 501.
Pharyngitis, hot claret gargle for, 221.
Phelps, A. M., the wood corset, with improvements, for the treatment of lateral curvature and Pott's disease of the spine, 37.
Phenacetin, poisoning with, 108.
Phlegmasia alba dolens, 22.
Phosphorus, administration of, in rickets, 293; poisoning by, 607; poisoning by, permanganate of potassium for, 293.
Photomicrography, simple, 246.
Phthiriasis pubis, tallow for, 222.
Phthisical, colonization of the, 379.
Phthisis, alleged danger of counter-irritation in, 521. *See* also Tuberculosis.
Physician, deportment of, 56.
Physicians, prevention of alien, from practising in New York, 437.
Physiological chemistry, advances in, 295.
Physiology in 1891, 308.
Physostigma in hiccough, 181.
Picrotoxin in night sweats, 307.
Pierson, William, epithelial carcinoma of the kidney, 463.
Pineapple juice, 184.
Piperazine, local solvent action of, on uric-acid concretions, 436.
Pitchfork wound of the neck, 166.
Pityriasis versicolor, antiseptic treatment of, 149.
Placenta, retention of, for four months, 52.
Plagiarism extraordinary, 648.
Plague, the, in London, 84.
Pleurisy, traumatic suppurative, 247; with effusion of the left side, dysphagia in, 112.
Pleuritic exudation, sodium salicylate in, 180.
Pneumo-hydrothorax, 156.
Pneumonia, acetate of lead in, 222; acute lobar, in the light of bacteriological investigation, 584; chloral in, 150; digitalis in, 98; modern treatment of, 16; Parisian methods of treating, 439; treatment of, 141, 402, 416, 607; varieties and treatment of, 385.
Poisoning case, the Harris, 152.
Poisonous odors in plants, 314.
Poliomyelitis, chronic ascending anterior, 157.
Pooley, Thomas R., perichondritis auriculæ of both ears, 148.
Porro's operation, 700, 724.
Potassium bromide, accumulation of, in the tissues, 543.
Pott's disease of the spine, abscess in, 719; the wood corset in the treatment of, 37.
Powers, George H., a new procedure in

extraction of cataract in its capsule, 166.
Practice, medical, the financial side of, 72.
Practitioner, decadence of the general, 325.
Practitioners' Club of Chicago, 167.
Practitioners' Society of New York, 187, 245, 357, 413.
Pregnancy, diagnosis of, between the second and eighth weeks by bimanual examination, 333; extra-uterine, 77, 134, 159, 160, 319, 332; ovariotomy during, 701.
Prescription pads, regulating, 296.
Prescriptions and prescription-writing, 614.
Prince and doctor, 636.
Prize, Alvarenga, 185; Broca, 47; Colombat, 243; for an essay on demography, 242; for an essay on temperance, 215; of the Medical Society of the County of New York, 243; Sentin, 648.
Prizes, dermatological, 709; of the French Society of Hygiene, 270; of the Paris Academy, 46; of the Spanish Academy, 517.
Professional manners, 382.
Professions, success in two, 336.
Professor and doctor, title of, 549.
Prohibition, the communion and, 130.
Prophylaxis and therapeutics, relations of bacterio-chemical results to, 664.
Prostate, monstrous hypertrophy of the, 348; neuroses of the, 490.
Prostatectomy, 491.
Prostatitis, treatment of chronic, 575.
Prostitution, proposed congress for the study of, 28.
Pruritus, treatment of, 222; vulvæ, treatment of, 491, 607.
Psilosis, discussion on, 556.
Psychiatrico-criminological museum, 448.
Psychic medium, facts bearing upon the nature of a, 459.
Purgatives in intestinal dyspepsia, 383.
Pus, absorption of, by the system, 249.
Pyorrhœa alveolaris often diagnosed as facial neuralgia, 178.
Pyosalpinx following miscarriage successfully removed, 405.

Q

Quack, punishment of a, 140.
Quackery, the new, 658.
Quacks, war on, 353.
Quatrefages, Professor, death of, 184.
Quinine, an underproduction of, 242.
Quintuplets, a case of, 185.

R

Rabies, treatment of, by an intravenous modification of Pasteur's method, 550.
Rachitis, incipient, death from laryngismus stridulus, in, 588.
Racial immunity and inoculation, 430.
Radius, forward dislocation of the, 517; treatment of uncomplicated fractures of the base of the, 703.
Railway carriages, warming, 447.
Railway casualties in the United States, 154.
"Record," a permanent, 44.
Rectum, some affections of the, 380, 543.
Reflex, a case of nasal, 249.
Refraction, mydriatics in the determination of errors of, 325.
Regular medical college, definition of a, 354.
Reproduction, absence of all organs of, 41.
Resorcin in diarrhœa and vomiting, 98.
Respiration, artificial, in asphyxia of the new-born, 393.
Rest and travel as therapeutic agents, 128.
Retina, operative treatment of detachment of the, by Schöler's method, 62.
Retinitis treated by methylene blue, 352.
Rheumatism and chorea, seasonal relations of, 642; and chorea, relations of, 588; changes of the blood in, 274, 723; salophen for, 131; the fever of chronic, 98; treatment of, 373, 419, 576, 607.
Richardson, T. G., resolutions in memory of, 659.
Richmond, Nelson G., placenta retained four months, 52.
Riley, Henry A., legislation on medical and health matters in the various States in 1891, 427, 513, 629; medical legislation in 1891, 9, 315.
Ringworm, treatment of, 127.
Riviera, letters from the, 79, 304, 360, 387, 442, 498, 614; ways of invalids on the, 168.
Robinson, Beverley, on the use of creosote in the treatment of pulmonary phthisis, 229.
Rockwell, A. D., a new electro-therapeutic electrode, with experimental observations, 536.
Romero, José Maria, death of, 186.
Roosa, D. B. St. John, astigmatism, its relative importance in asthenopia due to errors of refraction, 337.
Rose, A., the modern Greek language, 476.
Rosenberg, Julius, the management of labor without vaginal examinations and without prophylactic vaginal douches, 95; the treatment of hemorrhage by the infusion of saline solutions, 163.
Rosman, John G., death of, 466.
Ross, James, death of, 348.
Roy, Philip S., the harm of nauseating expectorants in the bronchitis of children, 138.
Royalty and their medical attendants, 161.
Ruck (von), Karl, the clinical results from the use of Professor Klebs's tuberculocidin, 685.
Russian students of medicine, 712.
Russian universities, 307.

S

Sacro coccygeal tumor in a child three weeks old, 588.
St. John's Guild, 297.
St. Luke's Hospital, 212.
Salicylate of sodium in pleuritic exudation, 180.
Salicylic intoxication, 181.
Saline infusion, hot, 275.
Salipyrin, 312.
Salivary calculus, 28.
Salol, 543; dangers and antidote, 672; effects of, 98.
Salophene, a new anti rheumatic, 373.
Sangree, Ernest B., an easy birth, 461.
Sanitary science, 57.
Scabies, treatment of, 293, 607.
Scalenus muscle, 73.
Scarlet fever, followed by typhoid fever, 691; prevention of, 473; treatment of, 351.
Schalck, E., a case of anosmia, 292.
School children, health of, 383.
Schroeder, Henry H., the treatment of a cold, 113.
Schwarzschild, H. Davison, a case of palimptosis alternating with proptosis, following injury, 544.
Scoliosis, pathogeny and treatment of, 13; pressure myelitis in, 604.
Scott, M. T., suppurative perityphlitis—rupture into bladder and rectum—operation—recovery, 93.
Screw-worm disease, 98.
Scrotum, treatment of eczema of the, 420.
Seasickness, artificial, 693.
Secretary of Public Health, 100.
Semeleder, F., a strange medico-legal case, 463.
Senile gangrene, early high amputation for, 158.
Septicæmia, intestino-peritoneal, 246.
Sergin, Dimitrie, death of, 104.
Sex in education, 646, 724.
Sexual organs, relation of, to nervous disease, 587.
Seymour, Elbridge G., death of, 610.
Shaffer, Newton M., on elongation of the ligamentum patellæ as a factor in the production of certain knee troubles and difficulties of locomotion, 59.
Shallenberger, H. M., physostigma in hiccough, 181.
Sharp, L. N., sudden and profuse hemorrhage during labor, 166.
Shipboard, pure drinking water on, 84.
Ships, ventilation of the holds of, 420.
Shock in acute anæmia, intra-venous saline injection for, 159, 163; surgical, 159.
Siegfried, C. A., the non-contagiousness of leprosy, 277.
Sims, J. Marion, statue to, 438.
Singers, female, impairment of the voice in, due to diseases of the genital organs, 697; thorax of, 261.
Sinkler, Wharton, on hereditary chorea, with a report of three additional cases and details of an autopsy, 281.
Skin, absorption by the, 150, 542; transplantation of large flaps of, 633.
Skin disease, a new, 323; rare cases of, 157.
Skin-grafting by Thiersch's method, 23.
Skull, fracture of the, and drunkenness, 351.
Sleep, preternatural, 614.
Small, Sidney I., a case of hydrophobia, 110.
Small-pox in England, 592.
Smith, A. Lapthorn, a new flexible intra-uterine electrode for positive galvano-cauterization, 676.
Smith, David S., minute on the death of, 167.
Smith, E. H., a criticism on medical text-books, 138; the sanitary condition of Chicago, 676.
Smith, G. Tucker, a case of erysipelas, 108.
Smith, Stephen, suggestions in regard to reforms of the present method of performing the duties of coroner in the State of New York, 57.
Snake bite, chromic acid for, 336.
Snare, nasal, new method of fastening the wire in, 447.
Snow, L. B., total absence of all organs of reproduction, 41.
Soble, N. W., atropine in hæmoptysis, 11.
Somnal, dose of, 355; physiological and therapeutic action of, 286.
Specifics, origin and uncertainty of, 151.
Spermato-cystitis, 99.
Spinal cord, lesions of, areas of anæsthesia in, as a guide to localization, 642; paths of sensory conduction in the, 548; treatment of chronic diseases of the, 593.
Spine, extra dural tumor of, removed by operation, 290; fracture of the, 690; pressure myelitis from lateral curvature of the, 604.
Spitting, the evils of, 519.
Spleen, cure of enlarged, 607; traumatic rupture of the, 497.
Spontaneous combustion, so-called, 592.
Stafford, James, the cylindrical vaginal tampon-pessary versus other pessaries, 482.
Starr, M. Allen, the cerebral atrophies of childhood, with special reference to the operation of craniotomy for imbecility, epilepsy, and paralysis, 85.
Steenberg, Professor, death of, 578.
Stickler, Joseph William, epithelial carcinoma of the kidney, 463.
Stillman, Charles F., death of, 552.
Stillman, Frank L., two cases of purulent rhinal discharge, 180.
Stitt, E. R., report on wounds by Mannlicher bullets, 147.
Stomach, association of ulcer of the, with cardiac disturbances, 196; diagnosis of ulcer of the, 252; direct electrization of the, 105, 116, 142; gunshot wound of the, 668; lack of gastric juice, 650; measuring the capacity of the, 44; misconceptions and misnomers revealed by modern gastric research, 644; traumatic rupture of the, 497.
Stomatitis, bromo potassic, cured by chlorate of potassium, 150.
Strabismus, advancing the internal rectus muscle for divergent, 191.
Stricture, œsophageal, treatment of, by permanent tubage, 205; urethral, reflex neurosis from, 517; urethral, in the female, 516; urethral, in the female, reflex irritations and neuroses caused by, 34; urethral, operative treatment of, 159; urethral, two cases of, 165.

Strontium salts, danger of, 137.
Stroup, W. H., pitchfork wound of the neck, 166.
Struggle, the early, 51.
Study, Joseph N., some personal observations upon a case of fracture of the spinal column, 690.
Styptic, a new, 268; fibrin-ferment as a, 591.
Sublimate poisoning, 348.
Suicide club, 408.
Suicide during parturition, 695.
Suicides in Paris, 211; of physicians, 326.
Sulphonal, a large dose of, 384; dangers and disadvantages of, 633; best mode of administration, 47.
Suppuration due to septic sutures, 335.
Suppurative process, the, 307.
Supra-renal bodies, function of the, 298.
Suture, the crossed, 159.
Sweats, night, hydrastis canadensis in, 127.
Symphyseotomy, revival of, 18.
Syphilides, secondary, of the mouth, 279.
Syphilis, disastrous results of, 609; discussion on, 612; tannate of mercury in the treatment of, 6.
Syphilitic paraplegia, 285.

T

Tabes, treatment of, 593, 607.
Tachycardia, treatment of, 308.
Talipes equino-varus, open incision for, 157; practical points in the treatment of, 649.
Tampon, cylindrical vaginal, versus other pessaries, 482.
Tape-worm, expulsion of, by the mouth, 160; treatment of, 221, 420, 576.
Teeth, care of, in diabetes, 491; second-hand, 317.
Telephone, infection by, 660.
Temperance, von Moltke's plan for the promotion of, 711.
Temperature, high, in a hysterical patient, 405.
Temperatures, an explanation of some high, 531; unequal axillary, 240.
Tendon-sheaths and bursæ, some of the affections of the, 375.
Tendon-suture, multiple, 590.
Testator, a philosophical, 391.
Testicle, atrophy of, produced by torsion of the spermatic cord, 336; compression for swollen, 654; retained, 462.
Tetanus, a specific for, 126; antiseptic treatment of, 162; etiology of, 671.
Text-books, medical, a criticism on, 138.
Thacher, J., death of, 695.
Theatres, ventilation of, 42.
Theriaca, 560.
Thilanine in skin diseases, 293.
Thomas, T. Gaillard, a successful case of Cæsarean section, 534.
Thorax, the singer's, 261.
Thornbury, F. J., influenza and the latest bacteriological researches, 621.
Thorpe, E. J. E., pathological language, 530.
Thrombosis, cardiac, 404.
Thyol preferable to ichthyol, 420.
Tic, convulsive, nature and treatment of, 236.
Tidy, Meymoth, death of, 410.
Tinea versicolor, treatment of, 221.
Tobacco bacteria, the ptomaïne of, varies the flavor, 167.
Toe, little, future of the, 380.
Tongue-depressor, a satisfactory, 532.
Tongue, surgery of the, 705.
Tonsillitis, chloral gargle for, 221.
Tonsillotomy and its therapeutic efficacy, 68.
Tonsils, function of the, 150; hypertrophy of the, 300.
Tonsil-snare, an electric, 559.
Toothache, local application for, 222.
Tooth-extractor, the champion, 408.
Townsend, W. R., the necessity for early mechanical treatment of infantile spinal paralysis, 122.
Tracheotomy without the use of the tube, 107.
Trephining for relief of paralysis and convulsions, 23, 320.
Trichinosis, 498.
Tricocephalus dispar, 525.
Tripier, Léon, death of, 46.
Tritopine, 718.
Trocar and dilating cannula for abscess drainage, 503; for drainage, 335.
Trophoneurosis, a new variety of, 99, 347.
Tsang-Ding, the last of, 550.
Tubercle bacilli, dead, effects of on the body cells, 247.
Tuberculin, 551; epitaph on, 307; failure of, in London, 132.
Tuberculocidin, 474; clinical results from the use of, 685.
Tuberculosis, acute miliary, and meningitis, 71; and alcoholism, 500; benzosol in, 576; conditions of cure in, 296; creosote in the treatment of, 229, 402, 419; dog-serum in, 550; elements of contagion in, 218; guaiacol in, 101, 295; in Buda-Pesth, 185; in cattle, quarantine against, 130; infectiousness of, 212, 218; latent, 358; methods to prevent the spread of, 273; new outlooks in the prophylaxis and treatment of, 561; prevalence of, in the United States, 219; prevention of, 75, 218; primary cutaneous, by direct inoculation, 712; processes which result in the arrest or cure of, 29, 105; surgical, 670; treatment of experimental, by tuberculin and other products of the tubercle bacilli, 640; vesical, 448.
Tuberculous lesions involving the joints, complications and sequelæ of, 344, 357.
Tuberculous sputum, dead bacilli in, 398.
Tucker, Ervin A., obstetrical science and architecture, 363.
Tucker, Joseph Clarence, death of, 46.
Tumenol, 591.
Turbinated bone, middle, asthenopia and headache due to hypertrophy of the, 462.
Turkey, medical schools in, 167.
Typhoid fever, chloride of iron in, 576; cold-water treatment of, 638; erythema multiforme in, 347; following scarlet fever, 691; in Boston, 608; in infancy, 150, 555; in the Boston City Hospital, 626; intestinal perforation in, 348; treatment of, 413.
Typhoid poison, transmission and behavior of, 666.
Typhoid ulcer, perforation of, with adhesive and protective peritonitis, 156.
Typhus fever, a study of, 713; and famine in Russia, 592.

U

Ulcers of the Emin Pasha relief expedition, 43; of the leg, treatment of, 400; rodent, resorcin for, 221.
Umbilical hernia without true hernial coverings, 384.
Umbilicus, septic infection from the, 127.
Universities of the world, 252.
Ureter, adhesion of, to the peritoneum, 55.
Urethra, complete absence of, 292; operative treatment of stricture of, 159; primary cancer of the, 559; two cases of stricture of, 165.
Urethritis, chronic papillomatous, treatment of, 491; posterior, irrigation without catheter in, 544.
Urine, aluminium in the, 384; clinical examination of, 331; deposit of indigo in the, 708; incontinence of, in children, 13.
Urostigma dolarium, a new vegetable digestant, 308.
Urticaria, caterpillars, as a cause of, 726; of the throat, 8.
Uterine appendages, indications for, and results of removal of the, 267.
Uterus, amputation of the vaginal portion of the cervix, in cases of suspected cancer, 157; carcinoma and fibromata in the same, 525; drainage of, in chronic endometritis and metritis, with or without salpingitis, 49; electrode for positive electro cauterization of the, 676; fibroid tumors of the, 704; hysterectomy for prolapse of the, 23; importance of drainage in diseases of the endometrium, 160; lacerations of the cervix, 158; operative procedures in displacements of, 159; reproduction of the mucous membrane of the, 542; rupture of the, 247; rupture of, caused by divulsion, 547; spontaneous expulsion of fibroids of the, 1; stenosis of the cervix, intestinal obstruction following operation for, 23; vaginal hysterectomy for cancer of, 160; value of rapid dilatation of, in diagnosis and treatment, 529.

V

Vaccination as a prophylactic against influenza, 46; compulsory in Japan, 532; in Italy, 618; neglect of, in Guatemala, 56.
Vaccine lymph, the bacteriology of, 529.
Van Bibber, John, death of, 552.
Vanderpoel, W. B., a case of childbirth complicated by facial erysipelas, 691.
Van Valzah, W. W., the causation and treatment of chronic diarrhœa, 340, 358.
Van Wyck, William H., resolutions on the death of, 74.
Varicella, a second attack of, 167.
Varicose veins, abdominal, in a boy of sixteen years, 109; treatment of, 400.
Variola and vaccinia, identity of, 293.
Vaseline, warning against the use of, 620.
Vegetable alkaloids primarily elaborated as a protection against disease in the plant world, 164.
Venereal disease in the Italian army, 520; one way of preventing, 351.
Ventilation of the holds of ships, 420.
Vertebræ, tuberculosis of the lumbar, 525.
Vertigo of arterio-sclerosis, 667.
Vienna Medical Society, building for the, 502.
Vitaline, 660.
Vinton, Maria M., a case of myxœdema, 250.
Vitreous humor, curious formation in the, 127.
Vivisection, a plea for, 465; in Germany, 320.
Vocal cord, tumor of the, 252.
Voorhies, C. H., complete absence of the urethra, operation and cure, 292.

W

Walker, Henry F., some suggestions in the management of lung fever, 402, 416.
Wallian, Samuel S., an improved form of portable apparatus for evolving and purifying oxygen, 139.
War, health of the survivors of the, 153.
Warfare, modern, weapons of, 47.
Warner, R. E., death of, 46.
Washburn, W., some facts for the consideration of the Health Department, 559.
Washington, regulation of medical practice in, 153.
Water, drinking, bacteriological study of, 638; on shipboard, 84.
Weber, Leonard, the present state of treatment of the chronic diseases of the spinal cord, especially of tabes and neurasthenia, 593.
Webster, David, report of 136 cases of cataract extraction, with remarks, 121.
Weeks, John E., gouty eyelids, a case of rheumatic iritis, and a case of rheumatic kerato-iritis, 177.
Weir, Robert F., adhesion of the ureter to the peritoneum, 55; intestinal anastomosis (without rings) between the ileum and the sigmoid flexure for intestinal obstruction (neoplasm) in the transverse colon, 399, 418; remarks on sub-diaphragmatic and rectal abscesses of appendical origin, 173, 190.
Wells, Fred. Lloyd, sub-dural intra-cranial

hemorrhage (without fracture)—leptomeningitis—trephining—recovery, 541.
West, W. B., when is a man a father? 693.
White, J. Blake, a double nasal spray and vaporizer, 364.
Whitman, Royal, a consideration of some of the affections of tendon-sheaths and bursæ, and their relations to injuries and diseases of the joints, 375.
Whooping cough, antipyrine for, 386, 491; folk-lore remedy for, 28; treatment of, 98.
Wiggin, Frederick H., a case of perforative appendicitis complicated by pregnancy, 109.
Wiggins, Levi Olmstead, death of, 48.
Williams, George Herbert, fracture of the penis, 320.
Williams, W. Roger, alleged mammæ erraticæ, 193.
Wistar Institute of Anatomy, 382.
Woman dentists in Russia, 592.
Woman medical students in Russia, 725.
Woman, the nervous, 657.
